table of recommended daily allowances of specific nutrients, should receive official recognition in England and serve there as well as here as a guide in planning for nutrition. The table probably will also serve—it ought to serve—to guide what plans are made for feeding people everywhere. In that case the demand for milk, meat, fruits and other rich sources of the nutrients called for by the "yardstick" will tax resources to the limit. This raises questions whether foods now commonly available are used as economically as possible and whether foods not commonly in use but equally, or even more, nutritious could serve as supplements to common foods.

DAIRY PRODUCTS

Milk tops all lists of foods of high nutritious qualities, but wasteful practice enormously restricts its use for human food. Much milk is separated. The cream is used for making butter, and what is left is fed to animals or discarded. Until quite recently, only 12 per cent of the skim milk produced in the United States was used for human food. Objection to skim milk is mainly due to prejudice and is based on the erroneous conception that skimming removes the major value of the milk. A

market for dried skim milk is growing among commercial manufacturers of bread and several other processed foods, but a public demand for such a product has not existed. In the United States alone some fifty billion pounds of skim milk is largely wasted every year. How much of this is simply thrown away is not known. Much is fed to animals, but this is waste because the nutrients in skim milk, pound for pound, equal those of muscle meat, and it appears that 10 pounds (4.5 Kg.) of the nutrients of skim milk is required to produce 1 pound (0.5 Kg.) of food nutrients in the form of pork.² Other less costly feed would do as well for hogs.

The quart of liquid milk a day for children and the pint for adults, as recommended in much nutrition teaching, is more than many family budgets will allow, but why insist on liquid milk? Milk can be distributed as dried whole milk for much less cost and dried skim milk, which is relatively little perishable, could be sold for about a tenth the cost of liquid whole milk. The fats of milk except for a content of vitamin A, are not superior to other less expensive fats, and vitamin A can be found in much less costly foods than milk.

Most diets not providing milk afford less calcium and less riboflavin than are called for by the recommendations of the Food and Nutrition Board, yet many persons dislike milk and never drink it. A great advantage of dry skim milk is that it can be mixed with other foods in cooking, so that the consumer gets it painlessly. Indeed, much more milk solids can be put in bread, cakes and puddings by using dry milk powder than when liquid milk is used. The water in liquid milk limits the amount that can be added. The taste of reconstituted dry milk is less attractive than that of liquid milk, but the taste of custards and other cooked foods made with dry milk differs not at all from, or is superior to, the taste of similar products made with

3. Abbott, J. S. The Food Value and Economics of Skim Milk. *Am. J. Pub. Health* 30: 237-239 (March) 1940.

liquid milk. Buttermilk is also highly nutritious, matching skim milk in its content of vitamins and minerals.⁴ It also can be dried and thus distributed more economically.

The delicious taste of butter assures its marketing. However, to produce milk, as has been the custom, only for its butterfat has no advantage from the standpoint of nutrition and is grossly unsound economically, even for the producer.

Cheese mostly represents the cream in milk.⁵ Superior as a food because of the high biologic value of its protein and because of its content of calcium, cheese could be more largely used with great advantage. Most persons like it, but city dwellers take too little of it. The European peasant makes much more of cheese. It represents a substantial portion of his diet, and large consumption of cheese undoubtedly contributes to the proverbial vigor of the pastoral peoples of Asia and the Balkans.

Left over from the milk when cheese is made is whey. The water of the milk is in the whey, but with it part of the protein—the lactalbumin—some of the mineral matter and most of the vitamins, yet whey is mostly thrown away by manufacturers of cheese. In late years dried powdered whey has found a place in poultry feeds and in candy manufacture. Much more dried whey could be used for human food, and none should be discarded. It is reported that in Germany no milk products may be thrown away and none may be used for feed without a special license.

Sugar is not among the recommended foods. Its recent rationing will not provoke a hardship, for sugar supplies nothing in nutrition but calories and the vitamins provided by other foods are supplied by sugar to liberate these calories. One of the worst of the many bad food habits that Americans have acquired is their use of sweetened carbonated beverages. Many persons take such beverages by the half pint many times a day, with a resulting excessive consumption of sugar. The suggestion has been made⁶ that whey after removing its protein be incorporated in these beverages. By such means the minerals and vitamins of whey could make these drinks nutritious.

MEATS AND FISH

Next to the dairy products on the list of better foods come meat and fish, but in their use economy has been neglected. There is no evidence that the nutritive value of muscle meat differs significantly from one part of the animal to the other, yet small food budgets are regularly taxed by purchases of expensive cuts when thrifty cuts would do as well. Furthermore, the most nutritious parts of every carcass are seldom chosen by the customer and go to making fertilizer or feed. The blood, lungs, stomach, liver, pancreas, kidney, brain and heart are spurned by many persons. In southern China a suitable gift for a prospective mother is a pair of pig's feet. She will hope by the time the baby is born to have accumulated perhaps two dozen pairs to help support her demand for calcium during lactation.⁸

In the first world war the complaint was made by Reese⁹ that Americans had acquired 'a lot of silly ideas' about what is fit for food and what is not. Thereupon Reese advocated the use of certain reptiles such as turtles, lizards, snakes and even alligators. A happy habit of more primitive man was to devour whatever could be eaten in the carcass of his kill. He thus obtained the organ meats as well as muscle. The Navajo, for example, who in contrast to many other Indian groups has retained his vigor despite proximity to the white man's civilization, consumes all vestige of the sheep or goat he kills and exhibits a decided preference for the contents of the abdomen.¹⁰ He eats the organs first. The modern American credits the ancient Greeks with a high state of culture, yet Cornwall¹¹ found references in the *Odyssey* to many foods men spurn today—foods such as roasted entrails and goat's stomach filled with blood. There is current discussion of deficiency of certain lipoids in the diet of more civilized races. A return to these food habits of the ancient Greek and modern Navajo would at once correct such dietetic error, for the lipid content of organ meats such as liver is high. Much could be done to improve the nutritive quality of processed meats by including in them organ meat and blood. Blood sausage (*blutwurst*) is popular in Germany. The dog food manufactured by American packers, containing much of what they designate as offals, is demonstrably superior in nutritive value to most of the meat they can for human food.

The nutritive values of fish are as high as those of meat, except perhaps for iron.¹² The livers of many fish besides the cod are rich in vitamins A and D, also the body oils of fish contain these vitamins. The flesh of fish is also rich in vitamins of the B groups to such an extent that Goldberger and Wheeler¹³ found salmon to be effective for preventing pellagra. However, many fish equal in nutritive value to fish that are popular in American markets are neglected, notably the carp. Smoked carp is a delicacy in Europe, and carp culture in Germany is an industry of importance. Raising carp is said to be as profitable as raising pigs. American streams and fresh water lakes are full of rough fish which could be utilized for human food.

The huge oyster shell mounds of the Atlantic coast seem to testify that the aboriginal American made more use of oysters than happens now. A nutritional advantage in the oyster, which applies also to the clam, the lobster, the crab and the shrimp, is that it is eaten whole, so that the valuable nutrients of the internal organs are obtained. Pease¹⁴ maintained that the nutritive value of oyster meats is a little higher than that of cow's milk, owing to a high content of calcium, iron and other minerals and all the vitamins.

Fairchild,¹⁵ on a tour of the world, found giant snails as large as a man's fist offered for sale in Ceylon and Africa. They were considered a delicacy. He thought they might be raised in the Everglades of Florida for consumption in America.

For mention also without prejudice is the possibility of finding protein foods among the insects Wakefield and Dellinger,¹⁶ in the feces of pre-Columbian bluff dwellers of the Ozarks, found residues of insects. A modern primitive, the Bushman, considers appetizing the eggs of termites.¹⁷ Veirill¹⁸ has written that the grasshopper and the cricket were periodically important as foods for the Indians of the western plains, and in the West Indies a large white grub found in the pith of palm trees serves as food. These grubs when toasted are said to taste like roasted chestnuts. Even the ancient Hebrews, strict as they were in their choice of foods, looked with favor in times of famine on the locust.¹⁹ The nutritive value of insects must be high. The taste may not be bad. Insect culture might some day become a part of food economy.

Should the time ever come when the land fails to provide enough good protein to meet all human needs, an unlimited supply can be found in the sea. The catch of fish has limitations, but ubiquitous in the oceans is the zooplankton, which could be harvested and would provide a first class human food. However, the technical difficulties involved are rather overwhelming. The estimate has been made by Clarke²⁰ that the human requirement for calories for one individual could be met only by all the plankton in a volume of water "equal to a football field filled to a depth of 1 meter and a half."

More practical than plankton as a source of proteins is the micro-organism yeast. A by-product now and mostly thrown away by brewers, yeast could be grown in limitless amounts. Dried yeast is largely protein, 40 to 55 per cent. Most of the nitrogen free remainder is material consisting of a mannose polysaccharide. The amount of fat is small, from 1 to 3.5 per cent, but this is rich in sterols. The content of vitamins of the B complex is very high, some vitamin A is present and much ergosterol, which by ultraviolet irradiation can be changed to vitamin D. This is important because almost no foods other than fish liver oils provide significant amounts of vitamin D. Among the amino acids found in the proteins of yeast are alanine, valine, phenylalanine, glutamic acid, aspartic acid, leucine, oxyproline, aspartic acid, cystine, methionine, tyrosine, proline and tryptophan. The percentage of these ranges from 10 down to 0.5 in the order given. The diamino acids present include lysine 10 per cent, arginine 5 per cent and histidine 5 per cent.²¹

Some brewers' yeast is on the market now, sold mainly as a source of vitamins. The armed forces are receiving yeast in peanut butter as an optional spread for bread. The yeast taste is disguised by that of the peanut. Analysis of samples of such yeasted peanut butter (20 per cent) indicates a composition of approximately 32 per cent protein. The samples contain per gram around 30 micrograms of thiamine, 16 micrograms of riboflavin and 250 micrograms of nicotinic acid. Thus an ounce (30 Gm.) of such peanut butter should provide about 10 Gm. of valuable protein, about half the recommended daily allowances of thiamine and

nicotinic acid and a fifth of the recommended daily allowances of riboflavin.²¹

Two products, mixtures of vegetables and brewers' yeast, are listed in Accepted Foods.²² Bakers' yeast also has virtue as a food for persons who can eat it without abdominal distress. It is much less rich in thiamine than brewers' yeast, also some question remains as to the utilization by man of the vitamin B complex in fresh yeast.^{23a} A high thiamine bakers' yeast has recently been made available to fortify the dough of enriched bread.

The bitter taste of yeast and some aftertaste present complications to the use of yeast as food, but these objectionable qualities can be overcome. Some special yeasts have very little bitterness, and autolyzing yeast provides a product with a taste like meat. The possibilities of yeast as human food deserves more technological attention. Two major defects in many modern diets are relatively small provision of certain vitamins of the B complex and insufficiency of biologically superior protein. Both deficiencies could be limited by using yeast as food.

FRUITS

Another basic nutrient deficient in many diets is ascorbic acid, vitamin C. The trouble mainly comes from lack of fruit in diets, especially lack of citrus fruits. The tomato is good as a source of ascorbic acid, but many fruits such as apples and pears, most of the vegetables, milk and meat are far from rich as sources of this vitamin. However, citrus fruits and tomatoes, while grown abundantly in certain sections, are bulky, perishable commodities and hence expensive to distribute. Ascorbic acid can be made synthetically at relatively small expense, and it may prove to be desirable to add the synthetic vitamin to jellies, jams and other fruit preserves in such amounts as to bring the final content of ascorbic acid to that of ripe tomatoes.

Among less common foods which are rich in ascorbic acid is the black currant. Two ounces of black currants, cooked, according to Oliver,²³ will meet an individual's vitamin C requirements. The reference probably applies to minimal requirements. Consumed raw, watercress and strawberries are good sources of ascorbic acid, providing approximately 60 mg. per hundred grams. The edible hips of the wild rose are becoming famous for their content of this vitamin.²⁴ Thone²⁵ has suggested that the hip could be increased in size and developed commercially. Verrill,¹⁸ whose thesis is that North Americans should use more foods from South America, mentioned some of the unusual tropical fruits now on sale at a few exclusive markets in this country. They include the mamey, sapodilla, silkana, ceriman, papaya, anona, soursop, star apple and guava. Papaya has recently been suggested as a substitute for orange in Hawaii, as well as home made guava juice.²⁶ Guava has an especially high content of ascorbic acid. Goldberg and Levy²⁶ found

300 to 400 mg in each hundred grams of the fresh fruit, and on drying the guava fruit they obtained a powder of pleasant aromatic odor and practically no taste, with the rather phenomenal quantity of 2,500 to 3,000 mg of ascorbic acid for each hundred grams. A monograph on the guava is now in preparation by Webber of the California Agriculture Experiment Station.

VITAMIN TABLES

An important reason for the great amount of emphasis that nutritionists have placed on green and yellow vegetables is the content of beta-carotene in spinach, carrots, beet greens and other colored plants and roots. There is widespread misconception to the effect that chlorophyll has a place in animal nutrition. There is no evidence to support such a view. Carotene alone and not the chlorophyll of plants is converted in the animal organism to vitamin A. Few foods provide vitamin A ready made. Butter and fish liver oils are about the only sources. Butter may be excellent as a source or only fair, depending on the feed supplied to the cow. Assays run from less than 2,000 to more than 40,000 international units to the pound. The daily allowance of vitamin A for an adult man, as recommended by the Food and Nutrition Board of the National Research Council, is 5,000 units, and one of the greatest services the dairy industry could perform would be to standardize the vitamin A content of butter at some high level.

Interference with the fisheries of the world by the war has again directed attention to sources of carotene. Plant oils contain no preformed vitamin A and but little carotene. However, the pulp of certain yellow vegetables is very rich in carotene. An estimate by Barnett²⁸ suggests that 10,000 acres planted in carrots would yield 20 trillion units annually of vitamin A. This would amount of 4 billion daily human requirements, or enough to last a population of 100 million persons forty days. Another good source of carotene is the sweet potato, a prolific grower.

Many vegetables little known in North America deserve attention by the food economist. Some could be developed with advantage. The taro, for example, has a subterranean stem resembling the potato. The yield per acre is two to four times that of the potato and, measured in calories, may be ten times that of rice.²⁹ Taro is a common food in mid-Pacific islands, in parts of southern Asia and in South America. Varieties known as dasheens have been cultivated commercially in parts of the United States.³⁰ Taro in Hawaii is mostly eaten as a paste called poi. Fermented poi keeps well without refrigeration. Another vegetable of the tropics said to be high in nutrients is the breadfruit.³¹ Others are jautias or tamers, which serve importantly as food for the natives of the West Indies, and yuca, the edible root of the cassava plant, the source of tapioca. Widely used for food today in South America, as mentioned by Verrill,¹⁸ and cultivated by the Incas of Peru before the white man came, are the canna, the leren, the arikuna, the papa lisa, the oca and the arracha, as well as the better known peanut, the potato and the sweet potato.

Use of grass for human food again has come up for consideration since the present war began. Nebuchadnezzar was compelled to "eat grass as oxen" to atone for many sins. However, the benefit he derived, if any, was largely spiritual. The value of a food, as emphasized by Graham Lusk³² before World War I, depends mainly on the ratio of nutritive to non-nutritive components. Due consideration must be paid to a few special requirements, such as that for vitamin C. The citrus fruits and tomatoes, for example, although bulky, are of great importance in nutrition because of their content of ascorbic acid. Lusk once missed this point, as he later acknowledged.³³ He called tomatoes colored water, but by and large his early emphasis was right. The more nutritious foods are those with nutritive components high and non-nutritive components—namely, water and indigestible cellulose—low. Among the vegetables the tubers like potatoes and the legumes like peas and beans possess more of this quality than do the leaves of plants or grasses.

In times of famine, however, people will resort to whatever they can find to eat. In Russia, for example, in the last war not only grass but also the leaves and the bark of trees were eaten. In Germany and Russia enormous amounts of watery root vegetables, such as turnips, were consumed. In a population leaning too heavily on such foods, war edema is likely to develop. The type of protein obtained is poor and excessive water is ingested. Also the bulk of watery foods which needs to be ingested to contribute significantly to caloric requirements places an intolerable strain on the human intestine. The coarseness and amount of fiber some such foods contain may even interfere with absorption of what nutrients are present. The Germans as well as the Russians in the last war attempted to eke out dwindling supplies of flour by adding to this flour bran and chaff and even straw. By doing so they made bad matters worse. Nutrients diluted with large amounts of indigestible material are lost; they cannot be absorbed effectively.

Thus grass serves poorly as a human food. Even tender, leafy vegetables, valuable as a source of minerals and carotene, would not alone provide for human nourishment. Their protein would be inadequate and their water content excessive. However, all the leafy vegetables have a place as supplements to other foods, and tender young grass when dehydrated is excellent as a vehicle for several vitamins and salts. Such a product has been accepted by the Council.³⁴

THE CEREAL GRAINS AND THE LEGUMES

Relative ease and low cost of production and high content of energy yielding nutrients explain why cereal grains, rice and also corn have long contributed importantly to the diets of people whose civilizations have been based on agriculture. Wheat has been developed more than other grains. In England a hundred years ago wheat alone contributed nearly half of all the calories of the diet. Its consumption has been halved, and yet today it provides more calories for the English speaking world than any other food.

Oat culture could be stimulated with considerable advantage. Oats can grow much farther north than wheat, and oats provide a somewhat more nutritious

human food. The content of thiamine is higher and the protein is biologically superior. This explains the value of oats as feed for stock. Samuel Johnson's caustic commentary in his Dictionary that "oats in England is generally given to horses and in Scotland supports the people" illustrates how prejudice works hardships in nutrition. In England, then as now, just as in America, men were more concerned about good nutrition for their livestock than for themselves. The answer said to have been given to Samuel Johnson was "and where will you see such horses and such men?" The Scots became a hardy race on oats. So did the early Norse. Oatmeal is often mentioned in the Sagas.³⁵

Rye and barley are less popular than wheat in England and America. They are much more used in Europe. Rye is not superior to wheat in nutritive qualities, and rye flour, like white wheat flour, is generally overmilled. Also what there is of rye in most so-called rye bread is usually diluted with white wheat flour.

TABLE 2—Analysis of English Diets for Adult Men

	Calo- ries	Pro- tein Gm	Cal- cium Gm	Iron Mg	Vitamin A Inter- national Units	As- corbic Acid Mg	Thia- mine Mg
Middle class diet today	3,310	110	0.6	12.3	5,170	70	1.1
Poverty diet today	3,000	78	0.3	8.4	1,000	10	0.66
Middle (artisan) class diet 1876	2,130	120	0.2	4.0	1,100	0	1.77

From J. C. Drummond's *The Englishman's Food* London J. Cape 1940.

* A diet containing as little thiamine as this (0.72 mg. per thousand calories) provokes symptoms of severe beriberi. See Williams, R. D., Mason, H. L., Smith, D. F., and Wilder, R. V. Further Observations on Induced Thiamine (Vitamin B₁) Deficiency and the Thiamine Requirement of Man. *Arch. Int. Med.* 69: 721-735 (May) 1941.

† For moderate activity.

Decortication of the grains by modern milling methods has been unfortunate from the standpoint of nutrition. The stone mills of the past left in the flour a large proportion of its vitamins. The flour was coarse and not very white, but in content of thiamine and nicotinic acid it far surpassed the finer flour of the roller mills. The latter came into general use some seventy years ago. The adequacy in certain vitamins, notably thiamine, of the diet of the populations of England and America—the adequacy especially of the diet of that part of the population of these countries which because of smaller purchasing power consumes much bread—was largely affected in consequence of technology applied to milling grains without the benefit of direction by a science of nutrition. There was no such science when these modern milling methods started.

The effect of roller milling on the thiamine content of American diets has not been estimated. Presumably, however, it was much the same as that in England. Drummond's³⁶ calculation of the nutrients contained in diets past and present is shown in table 2. The comparison reveals that the diet of the middle class Englishman in recent years, while supplying more vitamin A and more ascorbic acid, contains little more than a third as

much thiamine as did the diets of the past. In other respects the differences are less significant. The greater use of green vegetables and fruits in recent times accounts for the increased supply of the vitamins A and C. The substitution, about 1870, of roller milled white flour for the coarser flour of the past and the increased use of sugar explain the smaller allowances of thiamine in the modern diet. The milling industry of the United States is thoroughly aware at last of the importance of retaining in flour more of the thiamine and nicotinic acid of wheat. This ultimately will be accomplished without loss of other qualities which people have come to like and to demand in flour. Until it is accomplished, which may take many years and involve perhaps a revolution in the milling industry, restorative additions of thiamine and nicotinic acid to white flour and bread should be demanded. Restoration to staples such as flour of nutrients removed in processing was recommended in 1939 by the Council on Foods and Nutrition of the American Medical Association.³⁷ The procedure as applied to flour and bread was later endorsed by the Food and Nutrition Board of the National Research Council. Flour now is standardized and controlled by the Food and Drug Administration. White flour which bears the label "enriched" must contain thiamine and nicotinic acid, as well as iron, in amounts which are believed to approximate those in flour as flour was milled a century ago.

The nutritional environment of enormous populations of the Orient, which largely depend on rice for food, also suffered badly from food technology applied without the benefit of science. Milling rice is much like milling wheat. The primitive milling methods removed the husks but left brown rice with much of the bran intact. The later milling methods removed the bran coats and with them much of the content of vitamins and salts. The later methods yielded so-called polished rice. An example of how misguided man can be was supplied by Hou,³⁸ who wrote that in the rice country of China where beriberi is endemic the quite nutritious soybean is used for field fertilization in the cultivation of the less nutritious rice. One can buy brown rice in American markets, but only at a premium. It spoils and hence its distribution costs are high. A better buy is what is called unpolished rice. Unpolished rice is said to retain about a half of the thiamine of brown rice. It keeps well and after cooking is almost as white as polished rice.

Food habits to a great extent depend on the availability of foods. The story of the pottage of lentils for which Esau son of Isaac, sold his birthright to his brother Jacob suggests that lentils were more used in ancient times than now. In Germany lentil soup is still in favor, yet in nearby Belgium lentils, which were distributed in World War I, were spurned by people who were starving. There is no disputing the nutritional excellence of lentils. Likewise meritorious as foods are peanuts and soybeans.³⁹ The proteins of these legumes are biologically complete, superior to those of any of the cereals. The vitamins of the B complex and minerals are abundant. The Japanese eat fresh soybeans from bags like candy.⁴⁰ A popular food in Hawaii is miso, a fermented mixture of soybean

and rice. The soybean is a staple in certain parts of China, and the statement frequently is made that in these regions beriberi and pellagra are unknown. In Germany, cultivation of the soybean and its processing for human food has become a major industry. A sausage known as bratling, made with skim milk and soybean, forms a mainstay of the German army ration.¹² In the United States the press cake that remains after expulsion of the oil from soybean, peanut or cottonseed is sold for feed or is discarded. The industries get their profit from this "premium oil," which in part is used for food, in part for other purposes. Yet the press cake contains nutrients which are almost, if not quite, as valuable as the nutrients of meat and can inexpensively be converted into soups and other very tasty foods. The cost of production of protein from soybean plants is little greater than a tenth the cost of production of meat protein, and the present relatively small annual crop of peanuts and soybeans in the United States would provide 70 per cent as much protein as does the meat supply.

CONCLUDING COMMENT

This very brief review will show that modern man could reconsider many of his food ways with immeasurable advantage. Greater and more economical use of milk and meat and the use of more organ meat and fish would help to raise the quality of diets. Some common foods can be improved and greater use of many uncommon foods would help provide more adequate nutrition. The world is full of food potentialities, and the anticipated demands for foods possessing superior nutritive qualities calls for a reevaluation of world supplies of food. The reevaluation, if based on the science of nutrition, should reveal the means of providing all that is required for the optimal nutrition of all the populations of the globe, which well may be prerequisite for world security and order.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
HOWARD A. CARTER, Secretary

AUREX MODEL C-B AND MODEL C-A HEARING AIDS ACCEPTABLE

Manufacturer: Aurex Corporation, 1115 North Franklin Street, Chicago.

The Aurex Model C-B (No. 20888) and the Model C-A (No. 20654) are alike in external features. The dimensions and weights of the various parts are as follows:

Microphone and amplifier unit: 5 by 2¼ by ¾ inches, weight 4.55 ounces.

Crystal receiver without earpiece, ¾ by 1 inch diameter.

Bone conduction receiver: 1½ by ¾ by ¾ inches, weight 0.32 ounce.

Two battery units were supplied, one having a 33 volt B battery, the other a 43.5 volt B battery. The former is 3¼ by 3¼ by 1½ inches, weighing 10.9 ounces, the latter is 3¼ by 4 by 1½ inches, weighing 14.4 ounces.

BATTERIES

Voltages and current drains

A battery, General Battery Company, EP 600, 15 volts, 80 milliamperes.

B battery, unmarked, 33 volts, 0.7 milliamperes.

B battery, unmarked, 43.5 volts, 1.3-1.4 milliamperes.

ACOUSTIC GAIN

The instrument has a single volume control, a sliding contact on the side. Both instruments submitted have a fairly low internal noise level and are reasonably free from acoustic feedback difficulties. With a custom fitted ear mold they can be set to full volume without feedback squeal. The C-A No. 20654 unit is less subject to feedback than the C-B No. 20888. The following give the order of magnitude of the acoustic gains with various combinations:

C-B 20888	128	256	512	2048	3000	4096
¾ full volume with 33 volt battery	Nil	Slight	30	40	24	11
C-A 20654						
Full volume with 33 volt battery	Nil	Slight	27	45	24	16

Using the bone conduction receiver, a hard of hearing subject with conduction deafness having an average loss of 45 decibels reports that conversational speech is comfortably loud with either instrument set at one-half volume, using the 33 volt battery.

ARTICULATION TESTS

The usual word and sentence lists were used with hard of hearing subjects at a distance of 5 feet in a quiet room. These tests showed satisfactory performance with both instruments using both the crystal receiver and bone conduction receiver.

Aurex Model C Hearing Aid

MECHANICAL FEATURES

The instrument was found to be well made and shows no serious mechanical defects.

The Council voted to accept the Aurex Model C-B and Model C-A Hearing Aids for inclusion in its list of accepted devices.

LINDE OXYGEN THERAPY REGULATOR, TYPE R-85, ACCEPTABLE

Manufacturer: The Linde Air Products Company, Chicago.

When submitting the Linde Oxygen Therapy Regulator, Type R-85, for the Council's consideration the firm stated as follows:

This regulator was prepared in response to demands from physicians and others for a satisfactory device which would be less expensive than the other types of Linde Regulators accepted by the Council.

The R-85 is a single stage regulator which embodies all the parts essential for proper operation and with the nonessentials and special finishes omitted. It has been listed as standard by Underwriter's Laboratories and the parts are practically the same as those of successful industrial regulators.

(The Linde Oxygen Therapy Regulator Type R-50, was announced as accepted in THE JOURNAL, June 11, 1936, page 130, and the Linde Oxygen Therapy Regulator Type R-51, in THE JOURNAL, June 9, 1934, page 1941.)

In its examination the Council found that the unit was compact. The materials of which the regulator is constructed and the manner of their assembly indicate sturdy construction and reliability.

The regulator was put in service with the oxygen therapy setup of a large hospital. There

was no evidence of any failure of function.

The Council on Physical Therapy voted to accept the Linde Oxygen Therapy Regulator, Type R-85, for inclusion in the list of accepted devices.

Linde Oxygen Therapy Regulator Type R-85

SERUM SICKNESS AND ANAPHYLAXIS IN MAN

Kojis,¹ who recently studied a series of 6,211 cases in which horse serum was employed for various infections, suggests that mortality from anaphylaxis to serum is much greater than the incidence generally quoted from Park for this country (1 to 50,000) and from Pfaundler for Europe (1 to 100,000). Five fatalities were noted in the present series, a mortality rate of 1 in 1,042, or just under 0.1 per cent. Why serum sickness develops in some cases and not in others still remains a mystery. Contributing causes suggested by this study are the kind of serum, the preparation of serum, the quantity of serum, the horse producing the serum, the race of the patient, the route of administration, repeated injections and the patient. The most important influencing factors were the kind and the preparation of serum, repeated injections and the patient. The administration of an injection during serum sickness is particularly hazardous. Of 3 patients in this series who had injections 1 promptly died and another was made distinctly worse. For this reason recognition of serum sickness following injection is important. The classic symptoms begin with slight tenderness at the puncture point for about a day. After a few uneventful days, usually from the fifth to the tenth day, a rash develops suddenly. This rash, most often an urticaria, is frequently associated with edema, fever, adenopathy and polyarthritides.

The relation between serum sickness and serum anaphylaxis is extremely close, the only real difference being the time interval. As suggested by Cook, a reaction is one of anaphylaxis if it occurs within an hour or less after the administration of allergen. In this series there were 41 patients with anaphylactic shock. An important advance in prevention of serum sickness and anaphylaxis has been the improvement in the manu-

facturing of serums, particularly by the Parientjev method of proteolytic digestion of serum by pepsin.

Kojis stresses the necessity of performing intradermal and conjunctival tests with horse serum each time the serum is administered, unless it is given daily. Thus, when the reaction to the intradermal sensitivity test was positive the incidence of serum sickness following inoculation with diphtheria antitoxin in his series was 4 times, of anaphylaxis 35 times and of mortality 11 times greater than when the reaction to the test was negative. If the reaction to the conjunctival test was positive the incidence of serum sickness was 5 times and of anaphylaxis 173 times greater. Secondary injections of diphtheria antitoxin increased the incidence of serum sickness by 50 per cent, while the anaphylaxis rate was 23 times greater than after the primary injections. Use of the intramuscular route increased the incidence of anaphylaxis 14 times, while use of the intravenous route increased it 62 times. Thermal reactions were decreased by 50 per cent through fractional dosage. There were, however, 6 deaths in this series directly due to them.

Kojis believes in the prophylactic value of routine administration of 5 minims (0.3 cc) of a 1:1,000 solution of epinephrine to every patient before serum is given regardless of his state of sensitivity. The 5 deaths which occurred all followed secondary injections, 1 on the eighth day, 3 on the fifteenth day and 1 on the seventeenth day. These fatalities, each following a secondary injection, together with their symptoms and the typical postmortem observations in 2 cases identical with those of experimental animals, demonstrate, Kojis believes, that anaphylaxis does occur in man.

HEREDITARY ISOAGGLUTINOGENS

Ferguson and his co-workers¹ of the department of genetics, University of Wisconsin, have demonstrated at least thirty different hereditary isoagglutinogens in the red blood cells of cattle. This suggests chemical complexities in human erythrocytes beyond demonstration by current routine clinical technique. The use of natural isolysins and isoagglutinins for the demonstration of individual specificity differences in human and lower animal erythrocytes was first suggested by Landsteiner.² Fishbein³ found that in man individuals could be separated into distinct groups depending on the presence or absence of one or more natural antigens in their corpuscles. In cattle, such natural isoagglutinogens also existed but appeared to be present in no special order, division into distinct blood groups being impossible. In order to account for this difference, Fishbein postulated the existence of "multitudinous

agglutinins" in bovine serum or the existence of numerous modifying physical or chemical factors the existence or absence of which was independent of corpuscle specificity

Using Levine's⁴ improved centrifuge technic for hemagglutination, Little⁵ was able to confirm this "multiplicity" but nevertheless was able to separate bovine erythrocytes into three overlapping groups, with numerous "anomalous reactions" or "aberrant types" In addition to the considerable overlapping between the major groups, classification was complicated by the frequent apparent coexistence of homologous agglutinin and agglutininogen in the same blood sample Moreover, bovine agglutinins were modified in their titer by the presence or absence of serum complement

Under the generous support of the cattle industry and of national and international research foundations, a detailed restudy of these multiple antigenic components in bovine erythrocytes was undertaken by the Wisconsin geneticists The technic adopted by them was the use of immune isohemolysins, formed as a result of repeated citrated blood transfusions in pedigreed herds By selecting closely related members of the same herd, such transfusions could be made with minimum toxic reactions Numerous transfusions have thus been made of daughter blood into its own mother, with only an occasional retransfusion shock Retransfusion with less closely related donor and recipient was frequently toxic, giving anaphylactic reactions characterized by muscular trembling, dyspnea, salivation, lacrimation and hemoglobinuria, with rectal temperature often rising to 104 F Serum drawn from the recipient about ten days after the final retransfusion was occasionally of high hemolytic titer for donor erythrocytes if tested in the presence of rabbit complement

The serum obtained by immunizing a cow against her own daughter's blood often contained but a single isohemolysin, a monovalent antibody incapable of fractionation by partial adsorption on related or nonrelated bovine erythrocytes Occasionally a bivalent, trivalent or higher polyvalent isohemolysin was produced, which could be reduced to a monovalent lysin by fractional adsorption Two years ago Ferguson⁶ reported the preparation of the first seven monovalent isohemolysins by this technic, since which time the number has been increased to thirty Each unit lysin presumably reacts with a single specific receptor in bovine erythrocytes

By applying these thirty monovalent "reagents," analyses have been made of the erythrocytic complexity of numerous groups of pedigreed cattle In one group of twenty-nine cows, for example, each specimen was found to contain from ten to fifteen recognizable erythrocytic unit antigens No two animals yielded

blood cells with the same combination of antigenic characters Identical antigenic complexes, however, were subsequently obtained by erythrocytic analyses of identical twins If these thirty cellular antigens represent the maximum number of hereditary specificities present in bovine erythrocytes, the calculated number of different individual combinations would be 2^{30} , or slightly over 1,000,000,000 "The addition of only a few more independently occurring antigens to the thirty now recognized would bring the calculated number of possible combinations to a staggering total, not even approached by the national debt" Antibodies against as many as twelve of these unit components (A, B, C, G, J, S, V, W, Y, Z, E' and G') have been identified in a single immune bovine serum At least four of them (A, S, V and E) may coexist in certain natural serums or may be produced by injecting bovine erythrocytes into rabbits In cattle, isoantigenicity seems to depend largely on variations in the capabilities of recipients to respond to alien chemical stimulants

The Wisconsin geneticists were particularly interested in applications of their thirty unit characters to problems of inheritance In one experiment 217 matings were made between parents both of which contained their arbitrary A character Of the 240 offspring resulting from these matings 217 (90 per cent) had A antigen in their erythrocytes while 23 (10 per cent) were A negative Assuming that character A is transmitted by a single hereditary gene and that in many of the matings both parents were heterozygous to the A character, these percentages would be in accord with mendelian expectations In the same experiment 119 matings were made between parents only 1 of which was A positive Of the 127 offspring resulting from such matings 76 (60 per cent) were A positive and 51 (40 per cent) A negative This also is in accord with mendelian predictions In control tests, 41 offspring born of parents both of which were A negative were all (100 per cent) A negative Practically the same percentage distribution of hereditary unit characters was obtained with matings between cattle with or without each of the twenty-nine other cytologic isoagglutinogens Without exception an antigen was not found in any calf from matings in which both parents lacked this character, a law which might have practical applications in cases of disputed parentage The Wisconsin group was also interested in the fact that the number of hereditary antigens thus far demonstrated by them is the same as the number (thirty) of pairs of chromosomes generally accepted as present in bovine sex cells⁷

The work of the Wisconsin geneticists is of suggestive clinical interest since it indicates the probable complexities of human erythrocytes that eventually may be demonstrated by improved laboratory technic

Current Comment

FREQUENCY OF ABORTION AND ITS EFFECT ON MATERNAL MORTALITY

For obvious reasons, reliable national figures on the frequency of abortion or of deaths from abortion have not been available. All the studies on this subject have been limited in scope and generally confined to hospitals or clinics located in larger cities. Recently Dunn¹ chief statistician for vital statistics of the Bureau of the Census, has reviewed the available information on the subject and subjected it to careful analysis. From this evidence he concludes that the number of deaths from abortion in the United States in 1940 may be estimated at between three and four thousand, which probably constitutes about 30 to 35 per cent of maternal deaths from all causes. Although the general rate for puerperal causes has been decreased, the death rate for abortion has probably not changed much. It is clear, therefore, that the role of abortion in maternal deaths is important and that its lowering would materially affect the number and percentage of maternal deaths from all causes.

ISOLATION OF A VIRUS OF EPIDEMIC KERATOCONJUNCTIVITIS

On February 7 THE JOURNAL commented editorially on the occurrence of epidemic virus conjunctivitis reported from Oahu, Hawaii.¹ Cultures and smears from conjunctival scrapings from some 50 cases failed to reveal any offending organism. A similar acute inflammatory disease of the eyes appeared somewhat later in epidemic form in the San Francisco shipyards, spread throughout the Pacific coast area and had reached the East Coast. According to Murray Sanders² the disease as seen in New York appears as an acute follicular conjunctivitis with enlarged and sometimes painful preauricular lymph nodes. In severe involvement the conjunctiva is extremely congested and chemotic, and transient pseudomembranes may appear. Symptoms appear four to five days after exposure. The results of bacteriologic studies of conjunctival scrapings have been essentially negative. Experimental studies reported by Sanders suggest that a possible specific agent of the nature of a virus has been isolated. The pathologic picture produced in mice by intracerebral inoculation of conjunctival scrapings of a patient suffering with this disease, while not unique, did not resemble that in other common virus infections. The infectious agent was maintained when brain emulsion from the second mouse passage was put into tissue culture. Serial subcultivation was possible only at room temperature and by the use of ground up tissue culture as inoculum. A human volunteer who received the mouse virus in his conjunctiva responded in four days with a mild conjunctivitis. When mouse virus was again applied to the same eye there was

observed four days later a typical picture of epidemic keratoconjunctivitis. Definite neutralization of the agent was obtained when it was mixed with serum of a patient who supplied the original material. The neutralizing power of the serum varied from 100 to 10,000 mouse doses. The serum of another patient, also recovered from epidemic keratoconjunctivitis, contained definite neutralizing antibodies. However, a third patient who had recovered from epidemic keratoconjunctivitis failed to show neutralizing antibodies. Sanders states that a second isolation of virus has been effected and that thorough investigation of the two strains is now under way. It is to be hoped that the investigation of these two strains will throw additional light on the specificity of the offending agent.

HOSPITAL STANDARDS FOR CARE OF CRIPPLED CHILDREN

Hospital care is being provided for crippled children under approved state plans in more than seven hundred state hospitals. During the calendar year ended Dec. 31, 1941 nearly a million and a half days of care were provided in these hospitals for more than 31,000 crippled children. In a discussion of the hospital standards in these institutions, Van Horn and Lesser¹ emphasize that it is reasonable to expect that a public agency charged with the responsibility for spending public tax funds for the purchase of hospital care should purchase such care only from hospitals meeting standards which are acceptable to the agency. Minimum standards for hospital care of crippled children adopted in 1936 under the Social Security Act provided, in essence, that hospitals should have a qualified physician certified by the American Board of Orthopedic Surgery on their staff, at least one qualified physical therapist on the staff, and one qualified nurse with experience in pediatric and orthopedic nursing. They should conform with the minimum standards established by the American College of Surgeons, should employ at least one qualified medical social worker and should have physical therapy equipment including a room equipped with at least an exercise table and some form of radiant heat. Additional standards have been added since, including registration by the American Medical Association, provision of adequate facilities for the protection and isolation of children suffering from communicable diseases, inspection for fire hazards and adequate fire protection, and facilities for pediatric and other specialty consultation and supervision. A number of state agencies have recognized the needs for certain additional requirements. As pointed out by these physicians of the United States Children's Bureau, there has been unquestionably gradual but steady improvement in hospital standards for crippled children. Nevertheless there is need for continued efforts on the part of both public agencies and hospital authorities to bring about further progress in this direction. Likewise, they say, there is urgent need in all sections of the country for a better understanding between public agencies and hospital authorities of their mutual interests and of their responsibilities to the state and community which they serve.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

SOLDIERS' AND SAILORS' CIVIL RELIEF ACT AMENDMENTS

PREPARED BY THE BUREAU OF LEGAL MEDICINE AND LEGISLATION

The Soldiers' and Sailors' Civil Relief Act was approved on Oct 17, 1940. Its purpose, as indicated in an analysis of it that was published in THE JOURNAL, Jan 24, 1942, page 306, was to free persons in military service from harassment and injury to their civil rights during their term of military service and thus to enable them to devote their entire energy to the national defense. Experience under the act, however, has disclosed many defects and shortcomings, and numerous bills have been introduced in the Congress dealing with specific problems that have arisen. A subcommittee of the House Committee on Military Affairs was appointed to study the various proposals and as a result of that study legislation was drafted, H. R. 7164, to extend the relief and benefits provided under the original act. This bill has now passed the House and Senate and was approved by the President on October 6.

IN GENERAL

The new law extends benefits to transactions that have occurred since Oct 17, 1940. It extends benefits to persons who serve with the forces of any nation with which the United States may be allied in the prosecution of the war and who immediately prior to such service were citizens of the United States. Persons who have been ordered to report for induction under the Selective Training and Service Act will be entitled to benefits during the period beginning on the date of receipt of such an order and ending on the date on which such person reports for induction. Any member of the Enlisted Reserve Corps who is ordered to report for military service will be entitled to benefits during the period beginning on the date of receipt of such order and ending on the date on which he reports for such service. The Secretary of War and the Secretary of the Navy are required to make provision in such manner as each may deem appropriate for his respective department, to insure the giving of notice of the benefits accorded by the act to persons in and to persons entering military service.

LEASES

Of particular interest to physicians is the new provision relating to leases. Under the original act no provision was made for the cancellation of leases, nor did the section relating to leases apply to leases on property used for office purposes. The new law applies to any lease covering premises occupied for dwelling, professional, business, agricultural or similar purposes in any case in which (a) such lease was executed by or on the behalf of a person who, after the execution of such lease, enters military service and (b) the premises so leased have been occupied for such purpose or for a combination of such purposes by such person or by him and his dependents.

Any such lease may be terminated by notice in writing delivered to the lessor (or his grantee) or to the lessor's (or his grantee's) agent by the lessee at any time following the date of the beginning of his period of military service. Delivery of such notice may be accomplished by placing it in an envelope properly stamped and duly addressed to the lessor (or his grantee) or to the lessor's (or his grantee's) agent and depositing the notice in the mails. Termination of any such lease providing for monthly payment of rent will not be effective until thirty days after the first date on which the next rental payment is due and payable subsequent to the date when such notice is delivered or mailed. In the case of all other leases, termination will be effected on the last day of the month following the month in which the notice is delivered or mailed, and in such case any unpaid rental for a period preceding termination shall be proratably computed and any rental paid in advance for a period succeeding termination must be refunded by the lessor (or his assignee).

On application by the lessor to an appropriate court prior to the termination period provided for in the notice, any relief granted by the act will be subject to such modifications or restrictions as, in the opinion of the court, justice and equity may in the circumstances require.

Any person who knowingly seizes, holds or detains the personal effects, clothing, furniture or other property of any person who has lawfully terminated a lease covered by the act or in any manner interferes with the removal of such property from the premises covered by the lease, for the purpose of subjecting or attempting to subject any of the property to a claim for rent accruing subsequent to the date of termination of the lease, or attempts so to do, will be guilty of a misdemeanor and punishable by imprisonment not to exceed one year or by fine not to exceed \$1,000 or both.

STORAGE LIENS

A new section clarifies the original act in connection with the protection of persons coming into service from foreclosure of storage liens on household goods stored for the period of military service. No person may exercise any right to foreclose or enforce any lien for storage of household goods, furniture or personal effects of a person in military service during such person's period of service and for three months thereafter except on an order previously granted by a court. In such a proceeding the court may, unless in the opinion of the court the ability of the defendant to pay the storage charges due is not materially affected by reason of his military service, (a) stay the proceedings or (b) make such other disposition of the case as may be equitable to conserve the interest of all parties.

BENEFITS ACCORDED DEPENDENTS

The dependents of a person in military service will be entitled, on application to a court therefor, to the benefits accorded to persons in military service in connection with rents, instalment contracts, mortgages, liens, assignments and leases, unless in the opinion of the court the ability of such dependents to comply with the terms thereof has not been materially impaired by reason of the military service of the person on whom the applicants are dependent

INSURANCE PREMIUMS

The benefits of the act in connection with insurance premiums are extended to policies up to \$10,000 face value. In order to obtain the benefits, the insured must make written application to the Administrator of Veterans' Affairs. If the insured is outside the continental United States, excluding Alaska and the Panama Canal Zone, the beneficiary may apply for the benefits. The term "policy" is defined to include any contract of life insurance or policy on a life, endowment or term plan, including any benefits in the nature of life insurance arising out of membership in any fraternal or beneficial association. The policy must not provide for the payment of any sum less than the face value thereof or for the payment of an additional amount as premiums if the insured engages in military service. It must not contain any limitation or restriction on coverage relating to engagement in or pursuit of certain types of activities which a person might be required to engage in by virtue of his being in military service. The policy must (1) have been in force on a premium-paying basis at the time of application for benefits and (2) must have been made and a premium paid thereon before Oct 6, 1942 and not less than thirty days before the date the insured entered into military service. The benefits are not applicable to policies or contracts issued under the War Risk Insurance Act, the World War Veterans Act or the National Service Life Insurance Act of 1940

The Veterans' Administration is required to give notice to the military and naval authorities of the provisions of the act and must include in such notice an explanation of the provisions for the information of those desiring to make application for the benefits. An insured will have two years after the period of military service to repay premiums guaranteed by the government under the act. Interest on such premiums will be payable at the same interest rate as fixed in the policy for policy loans.

MISCELLANEOUS BENEFITS

The section of the original act which authorized in certain circumstances the repossession of automobiles of persons in military service is repealed. A new section prohibits interest at a rate in excess of 6 per cent on obligations of persons in military service incurred prior to his entry therein. A court may grant certain relief with respect to mortgages and taxes on property owned by persons not in military service when the rent for such property is not paid by dependents of persons in military service. The protection provided by the original act in respect of taxes on real property is extended to include taxes (other than income taxes) on personal property. The requirement that such taxes must have fallen due during the period of military service has been eliminated, as has also been the requirement that the person in military service must file an affidavit with the tax collector in order to prevent sale for delinquency without court action. A new section grants to persons in military service relief for a specified period after military service in order to enable them to liquidate their liabilities in an orderly fashion and not be subject to the accrual and payment of these liabilities all at one time. The court may grant an order staying enforcement of obligations either for a period of time equal to the period of military service or, in the case of certain real estate mortgages and contracts, for a period of time equal to the remaining life of the contract plus the period of military service.

ARMY

MEDICAL DETACHMENT COLLECTS
SEVENTY TONS OF SCRAP
METAL

The salvage officer at the Medical Field Service School, Carlisle Barracks, Pa., has collected and turned in during the present scrap drive more than 70 tons of scrap metal. The scrap obtained includes two German field pieces turned over by the Carson Long Institute, New Bloomfield, four small cannon formerly on the quadrangle at Carlisle Barracks, 20 pounds of razor blades, 51 pounds of tooth paste tubes, 6,660 pounds of tin cans, 1,245 pounds of copper, 2,002 pounds of brass, 950 pounds of aluminum, 162 pounds of lead and 134,760 pounds of iron and steel, according to a report made by Brig Gen Addison D Davis, in command of the Medical Field Service School.

MEDICAL OFFICERS FOR NEW
INFANTRY DIVISIONS

Twenty-eight U S Army medical officers completed a special training course at the Medical Field Service School, Carlisle Barracks, Pa. September 4, and, after brief graduation exercises, left for their posts in medical battalions of new infantry divisions which are being activated. This class was under training at the same time that classes were being conducted at various other army service schools to train officers of other branches similarly. According to a news release from the

Medical Field Service School, this course provided individual instruction so that each officer was trained specifically for the particular duty he will perform. Another class of medical officers arrived at Carlisle Barracks on September 7 to begin another special training course of instruction. Following are the names and the home towns of the officers who graduated on September 4:

Beckwith Harry S Capt Wins low Ariz	Matts Robert M, Capt Yuma, Ariz
Blair Clifford J Capt Oklahoma City	McArthur, Charles E Major, Cordele Ga
Bolton Eldon L Major Biloxi, Miss	Mervynne Robert D, Capt, Pasadena Calif
Bourne, John R Capt, Salt Lake City	Montgomery Samuel A Capt, Des Moines Iowa
Burstein Henry A, Capt Clevel- and	Moww Dick R 1st Lieut, Grandville Mich
Dietrich Hervey W Capt Madi- son Wis	Owen Duncan S 1st Lieut, Fayetteville N C
Dougherty Cary M Capt, Jack- son La	Powell Eppie C Major, Golds- boro N C
Hebert Thomas E, Capt Cov- ington La	Price Douglas W Capt, Napa nee Ind
Howard Glenn T Capt, Bruni, Texas	Rack Morris A, 1st Lieut, Mc- Keesport Pa
Johns Sydney L Capt Crifton Pa	Siehlowitz Alvan Major, Moose Lake Minn
Kilgore, Byron Jr 1st Lieut, Danville Ind	Shapiro Isadore A Capt Toledo, Ohio
Kistler James J, Capt, LaPorte Ind	Smollar Leo Capt Chicago Stern Louis S Capt West
Locklin, Walter K, Capt, Hart- ford Mich	Stiles Wendel A, Major Dallas Texas
Maril William D, Capt Okla- homa City	

EIGHT HUNDRED OFFICERS GRADUATE AT CARLISLE BARRACKS

The Medical Field Service School at Carlisle Barracks, Pa., graduated a class of 571 officers in the medical department, September 29, after completion of a special course to qualify them for duty with troops in the field. Among the students were three colonels, two lieutenant colonels, twenty majors, 129 captains and 352 first lieutenants, all of the medical corps in addition to officers of the dental, veterinary, sanitary and medical administrative corps. The course included training in map reading, sanitation, logistics, administration and military art. The graduation ceremonies were attended by hundreds of relatives and friends of the members of the class. The commandant, Brig Gen Addison D Davis, delivered an address stressing the importance of these studies, and Col Albert S Dabney, medical corps, assistant commandant of the school, sketched the history of the school and of Carlisle Barracks.

On September 26 the Medical Field Service School graduated 241 new officers as second lieutenants in the medical administrative corps. These officers will take over administrative duties in medical units and thus enable the army to relearn medical officers for more strictly professional duties. The Rt Rev Oliver James Hart, a chaplain in the first world war and also a chaplain in the present war until honorably discharged to accept the appointment of Bishop Coadjutor of Pennsylvania, delivered the graduation address in the presence of many relatives and friends of the new officers. Bishop Hart is an uncle of Second Lieut Joseph E Hart of York, S C, a member of the class, and a brother of Col William Lee Hart, M C senior medical officer of the eighth service command. The oath of office was administered by Lieut Col Thomas G Hester, adjutant of the Army Medical Center, Washington, D C. Members of this class who had completed several months of special training were selected from the enlisted ranks for their outstanding performance of duty and ability. Major Gen James C Magee, Surgeon General of the Army, Washington, D C, sent a special message of congratulation to the new officers on completion of the course.

ARMY TO TRAIN PSYCHOLOGISTS TO SIFT ILLITERATE SELECTEES

A training course for civilian psychologists who are to test illiterate Selective Service men will be instituted soon under direction of the adjutant general at Fort Leavenworth, Kansas the War Department announced, September 24. Those successfully completing the course will serve in the army specialist corps, in which some of the prospective students already have been commissioned. The demand for psychologists is a result of a recently adopted army policy of taking illiterate persons into service when it is felt that the degree of illiteracy is no bar to successful completion of military training. The course offered at Fort Leavenworth in October will be attended by more than a hundred and fifty psychologists, who will receive general indoctrination in army methods and specific instruction in the examining devices used at induction stations. The psychologists will be assigned to induction stations throughout the country. To determine whether a selectee is acceptable, a three part screening process will be used. First an oral interview will be given in which men are passed immediately on the basis of their obvious qualifications or held for further examination. If the man fails to pass the initial interview, he receives a nonlanguage, visual classification, test which is conducted as far as possible in pantomime in order that the test may be fair to men who may be literate in their own language but unable to speak or write English. If on the basis of the first two tests the examining psychologist finds that the registrant is of marginal ability, at his option he may give a third screening designed to determine whether the selectee can follow oral orders, all simple, but of varying nature. Illiterates who prove acceptable for service will be assigned to units for which their occupational experience best fits them and will have an opportunity to attend night schools or such other extracurricular classes as may be practicable.

MAJOR GENERAL OF BRITISH ARMY VISITS CARLISLE BARRACKS

Major Gen Alexander Gordon Biggam of the British Army Medical Service visited Carlisle Barracks, October 1, and was guest of honor at the weekly ceremonial parade. Also in the reviewing party were Major Gen Charles R Reynolds, United States Army, retired, former Surgeon General of the Army and commandant of the Medical Field Service School from 1923 to 1931, and Col Frank S Gillespie.

General Biggam was recently director of medical services in Burma, formerly was director of a medical unit at Kasr-el-Aini Hospital, Cairo, and was professor of clinical medicine at a university in Egypt, examiner in medicine at the Kitchener School of Medicine, Khartoum, and at the American University of Beirut.

Colonel Gillespie, British army medical service liaison officer at the school, met General Biggam in Washington and accompanied him to Carlisle. Entering the Royal Army Medical Corps in 1912, General Biggam saw action in four major battles in France. He was named a king's honorary physician in 1937. He is an officer of the Order of the British Empire and a fellow of the Royal College of Physicians of London, also a commander of the Egyptian Order of the Nile.

GRADUATION OF OFFICERS AT CHEMICAL WARFARE SCHOOL

Ninety-nine medical officers were addressed by Major Gen James C Magee, the Surgeon General, at the graduation ceremonies of the first medical officers course, Chemical Warfare School, Edgewood Arsenal, Maryland, October 2. Under the direction of Brig Gen Ray L Avery and Col Milton T Hankins, commandant and assistant commandant of the school, and Capt Aubrey L Sparks, course director, the officers were instructed in basic chemical warfare agents, protection against toxic agents, diagnosis, pathology and treatment. The graduating officers, members of the medical corps, who ranged in rank from first lieutenants to majors, returned to their stations throughout the country to act as instructors to other medical officers. The course of study was the first of its kind to be given and its success has paved the way for additional classes to start immediately.

FATHER AND THREE SONS IN SERVICE

Dr John C Hubbard and his three sons, all formerly on the staff of the Hubbard Hospital-Clinic, Oklahoma City, have been commissioned in the medical department of the U S Army. The father, Major John C Hubbard, is now at the station hospital, Fort Sill, Okla., a son, Major Ralph W Hubbard, was taken prisoner by the Japanese in the Philippine Islands, Major John R Hubbard is chairman of the medical examining board and on the board of induction at Oklahoma City, while the other son, First Lieut William E Hubbard, is at the School of Aviation Medicine, Randolph Field, Texas.

AVIATION PHYSIOLOGISTS

A course of instruction to qualify air corps personnel for duty as aviation physiologists began at the School of Aviation Medicine, Randolph Field, Texas, September 28. Following is a list of the students enrolled:

1st Lieut Bentley R Baker, Medical Corps	1st Lieut Nathan Rakieten, Air Corps
2d Lieut Clarence A Maaske, Air Corps	1st Lieut Clark A Sleeth, Medical Corps
1st Lieut Victor J Monke, Air Corps	2d Lieut Ralph I Smith, Air Corps
2d Lieut Ferrin B Moreland, Air Corps	1st Lieut Louis A Toth, Air Corps
1st Lieut George J Pastorius, Medical Corps	T/4th Gr Leonard Grumbach, Medical Department
	Pvt Clarence W McNutt, Medical Department

SENIOR MEDICAL OFFICER IN ENGLAND

In the list of nominations confirmed by the United States Senate late in September was that of Col Paul R Hawley, M C, U S Army, senior medical officer in England, to be a brigadier general.

EMORY UNIVERSITY HOSPITAL UNIT ACTIVATED

The Emory University Hospital Unit, U S Army General Hospital No 43, was activated on the first of September. The unit was organized more than a year ago and some of its officers had already gone on active duty. During the first world war the Emory University Hospital Unit, designated Base Hospital No 43, served in France at Blois about 75 miles southwest of Paris, where about 10,000 patients were treated before the unit was ordered home in 1919. In the new unit Dr Ira Ferguson and Dr Hugh Wood will be chief of the surgical and medical services, respectively, with the rank of lieutenant colonel. While Dr Ferguson has been the acting unit director, a regular army medical corps officer is to be assigned as the commanding officer of the unit.

The other physicians on the staff of General Hospital No 43, most of whom are from Georgia, are, according to the Fulton County Medical Society Bulletin, as follows:

Bailey Major Milus K. Atlanta	Funkhouser Capt (D C) W I Atlanta
Blackford Major Laurence M. Atlanta	Gibson Capt Roy C Columbus
Boling Major Edgar Atlanta	Gillespie Capt Robert H Atlanta
Bryan Major William W Atlanta	Hatch Capt Allen L Atlanta
Burke Major Benjamin R Atlanta	Hoffman Capt Byron J Atlanta
Claiborne Major Thomas S Atlanta	Hughes Capt (D C) Julius C Atlanta
Cross Major John B Atlanta	Inge Capt John H Atlanta
Hanner Major James P Atlanta	Marion Capt Robert I Atlanta
Harpole Major (D C) Homer J Atlanta	Myers Capt Guy A Atlanta
Joiner Major Hartwell Gainesville	Stone Capt Charles I Jr Atlanta
Lynch Major Albert O Atlanta	Weinberg Capt James I Atlanta
Martin Major John D Jr Atlanta	Wole Capt Bernard Atlanta
Monfort Major John M Atlanta	Croswell 1st Lieut (D C) Harry A Atlanta
Parker Major Francis P Atlanta	Everett 1st Lieut (D C) Stephen M Atlanta
Strickler Major Cyrus W Jr Atlanta	Gibboney 1st Lieut Harry S Camp Croft S C
Trumble Major William H Atlanta	Goodyear 1st Lieut William F Emory University
Agnor Capt Elbert B Atlanta	Rasmussen 1st Lieut Earl Fort McPherson
Armstrong Capt William B Atlanta	Smith 1st Lieut Fredrich A Jr Atlanta
Boland Capt Frank K Jr Atlanta	Vanner 1st Lieut William D Wheeler Capt Nicholas A Lafayette Ala
Boland Capt Joseph H Atlanta	White 1st Lieut Cecil G, Jr Carnegie Pa
Bosworth Capt Edward L Fort Story Va	
Chambers Capt James W LaGrange	
Ferguson Capt Anderson D Atlanta	

ILLINOIS HOSPITAL UNIT TO GO ON ACTIVE DUTY

The University of Illinois Hospital Unit, the twenty-seventh evacuation hospital, will go on active duty in October. Dr Charles B. Puestow, associate professor of surgery at the University of Illinois College of Medicine, Chicago, and now commissioned lieutenant colonel, for some weeks has been at the Walter Reed General Hospital in Washington for a period of training. Lieutenant Colonel Puestow, who organized the unit, will be director of this 750-bed mobile hospital. The other medical members of the personnel are largely University of Illinois alumni. At a party in honor of the unit at the Illinois Union Building on the Chicago Campus, September 22, the speakers were Governor Green, Mayor Kelly of Chicago, President Willard and the board of trustees of the University of Illinois, Admiral John Downes, commandant of the ninth naval district, Major Gen H. S. Aurand, commanding general of the sixth service command, Col. Chester L. Fordney of the U S Marines, Col. J. E. Bristan, surgeon of the sixth service command and other officers. Dr George W. Post Sr, president of the medical alumni of the university, was on the executive committee in charge of the arrangements. Following is a list of the personnel of the twenty-seventh evacuation hospital unit:

Lieut. Charles Allison Kankakee Ill	Capt. John O. Hanson Chicago
Capt. Robert F. Bedard Kankakee Ill	Lieut. Noel J. Hershey Miles Mich
Capt. Robert P. Hatchley D C Cook County Hospital	Capt. Herman Joffe Chicago
Capt. Daniel I. Bowers Peoria Ill	Dr. Robert M. Jones Chicago
Capt. Lawrence Breslow Chicago	Lieut. Karlton H. Kemp Tex
Lieut. John J. Brozman Chicago	Capt. John P. Klein Reed City Mich
Lieut. Joseph H. Buckley Chicago	Capt. William P. Kleitsch Chicago
Capt. George V. Byfield Chicago	Lieut. Sidney Lane Berrien Cent Mich
Capt. Clifford L. Carter Ottawa Ill	Capt. James W. Lewis Evanston Ill
Lieut. James H. Cross Chicago	Capt. Edward S. Lundgren Chicago
Dr. Roland Cross Jr New York (formerly of Chicago)	Capt. John H. Mathis Atlantic City N J
Dr. Howard I. Down Sioux City Iowa	Major Oscar F. Nadeau Chicago
Capt. Arthur H. Ericson N A C Chicago	Capt. Edward I. Schrey Chicago
Dr. Edward G. Evans Aurora Ill	Major Archibald Spelman Smithville Mo
Lieut. Charles F. Fildes Chicago	Capt. Thomas A. Weaver Jr Cincinnati
Major William J. Gillesby Effingham Ill	Lieut. Edward F. Webb Chicago
Lieut. Glen Goodwine N A C Chicago	Lieut. John C. Whittier New York
Lieut. Harold A. Grimm Chicago	

CIVILIAN DEFENSE

EMERGENCY BASE HOSPITALS

The Medical Division of the U S Office of Civilian Defense, through its regional medical officers and state chiefs of Emergency Medical Service, has now made emergency provision for the establishment of a chain of emergency base hospitals in the interior of all the coastal states. They will be activated only in the event of an enemy attack on our coast which necessitates the evacuation of coastal hospitals. Each base hospital will be related to the casualty receiving hospital which has been evacuated and it is expected that the staff will be recruited largely from the parent institution.

In order to meet a sudden and unexpected crisis without delay, arrangements have been completed with state authorities for the prompt taking over of appropriate institutions in the interior of the state for this purpose and with local military establishments for the transportation of casualties and other hospitalized persons along appropriate lines of evacuation.

More than a hundred and fifty hospitals in the coastal cities are in the process of organizing small affiliated units of physicians and surgeons, which will be prepared to staff the emergency base hospitals if they should be needed. These units are composed of the older members of the staff and those with physical disabilities which render them ineligible for military service, and of women physicians. In order that a balanced professional team may be immediately available the doctors comprising units are being commissioned in the inactive reserve of the U S Public Health Service so that, if called to duty,

they may receive the rank pay and allowances equivalent to that of an officer in the armed forces.

Dr. George Baehr, chief medical officer of the U S Office of Civilian Defense, states that the members of these affiliated hospital units will continue to remain on an inactive status for the duration of the war unless a serious enemy attack occurs in their region which necessitates the transfer of casualties to protected sites in the interior. Their commissions may be terminated on their request six months after the end of the war or sooner if approved by the Surgeon General. Such approval will be given in the event such officer desires active duty in the Army or Navy.

EMERGENCY MORTUARY SERVICES

The Medical Division of the United States Office of Civilian Defense has just issued Bulletin No 5 on Emergency Mortuary Services. The medical aspects of this bulletin are herewith condensed for the benefit of readers of THE JOURNAL.

In some air raids 40 per cent of the casualties may be fatal. Although the wounded require first attention, the dead should also be cared for promptly and inconspicuously. To facilitate identification each civilian in target areas of the country should be encouraged to carry an identification bracelet or necklace or metal identification pocket piece.

The necessary organization to clarify the lines of responsibility for handling the fatalities should be created by a conference called by the local chief of the emergency medical

service. The conferees should include the local medical examiner, coroner or similar official, the chief of police, the health officer and a representative of the private funeral directors and cemeteries. In large cities the morgue facilities and equipment should not be concentrated in one place. The main morgue should be centrally located, but tentative arrangements should be made for the use of skating rinks, gymnasiums, auditoriums or similar buildings for use as supplementary morgues, as necessary, to provide for total space to lay out bodies in the ratio of two per thousand of population in target areas. The normal morgue personnel should be supplemented by auxiliaries who have been trained by instructors. The staff of the emergency mortuary service should include a physician to confirm deaths and a coroner or other medical examiner's representative who has authority to sign death certificates and order disposal of unidentified bodies. Volunteer members of an emergency mortuary organization are to enroll with the Volunteer Civilian Defense Office and are entitled to wear the armband and insignia of the Emergency Medical Service, of which the Mortuary Service is a part.

Whenever possible a physician should examine the body before it is moved to the morgue so as to determine whether life is actually extinct. A physician should be charged with this duty, since to the inexperienced a condition of profound shock with extremely shallow respiration may give the appearance of death. Immediately after arrival at the morgue a physician should again examine each body to confirm the state of death, if there is any possibility of life, the body should be removed at once to a hospital. Unidentified bodies should be kept in a room separate from those already identified, so that a minimum number of bodies will be seen by persons viewing

the bodies for purposes of identification. Identified bodies should be released to private funeral directors as soon as they are claimed by responsible relatives.

The director of the Emergency Mortuary Service should call on the senior gas officer of the local Civilian Defense Office for technical advice and assistance in setting up procedures for handling bodies contaminated or suspected of contamination with persistent gases. It is important that the identification tag on such bodies be distinctly marked "gas case" in order that persons handling them will be warned to give them special treatment. Such bodies should be collected and moved only by workers wearing protective clothing and masks. All clothing and effects should be taken from the body, decontaminated and taken to the morgue. The body should be cleansed by approved methods before being admitted to the morgue. Persons who have performed these procedures must themselves subsequently go through the cleansing prescribed for decontamination squad members.

Other matters discussed in this bulletin include nonmedical personnel needed, such as recorders, morgue attendants and clerical assistance, transportation facilities, disposal of personal property, morgue storage, identification procedures, release and disposal of bodies (including emergency mass disposal of bodies) and completion and storage of records.

DR BAEHR VISITS ENGLAND

Dr. George Baehr, chief medical officer, Office of Civilian Defense, Washington, D. C., has gone to England to study Britain's emergency medical service and to confer with medical leaders. Dr. Baehr will be abroad for several weeks.

WAR PRODUCTION BOARD

ALLOCATION OF NARCOTIC DRUGS

Under a directive issued by the chairman of the War Production Board, October 6, the U. S. Bureau of Narcotics is authorized to allocate narcotic drugs in such manner and to such extent as it may deem necessary or appropriate in the public interest and to promote the national defense.¹ The bureau may regulate or prohibit the production, manufacture, sale, transfer or other disposition of narcotic drugs by any person who has acted in violation of any regulation or order prescribed by it pursuant to the directive and may require such reports and the keeping of such records and may make such investiga-

tions as it deems necessary or appropriate. The chairman of the War Production Board may from time to time delegate to the bureau such additional powers with respect to the exercise of control over narcotic drugs or may amend or revoke the delegation contained in the directive in such manner and to such extent as he may determine to be necessary or appropriate. No preference rating heretofore or hereafter assigned, applied or extended will have any binding effect with respect to any transaction in narcotic drugs unless the Bureau of Narcotics expressly so orders. For the purpose of the directive, the term "narcotic drugs" is defined to mean opium, coca leaves, cocaine or any salt, derivative or preparation of opium, coca leaves or cocaine.

¹ Federal Register, Oct. 7, 1942, p. 7938.

MISCELLANEOUS

DENTISTS IN TRAINING TO AID PHYSICIANS

Sixteen dentists in Flint, Mich., are taking special training in Flint hospitals at the invitation of the Genesee County Medical Society to enable them to assist physicians by performing certain medical procedures and thus to relieve the shortage of physicians created by the demands of military service. The training will qualify the dentists in obtaining blood for examinations, intravenous feeding, intramuscular injections, intravenous injections and obtaining blood from donors for blood banks. Several of the number are already qualified in some of these fields and are assisting in clinics and with Selective Service examining boards.

Colorado dentists are engaged in a similar program under the auspices of the Colorado State Dental Association and the Committee on Emergency Medical Service of the State Defense Council. The plan was initiated by the presidents of the State Dental Association and of the Denver Dental Association, in cooperation with the board of trustees of the Colorado State Medical Society. Facilities of the University of Colorado School of Medicine and the Colorado General Hospital have been made available for the instruction. A class of seventy

dentists has finished a course of lectures on anesthesia, and small groups are now assigned to the hospital for practical training. It is planned that the dentists shall return to the hospital at intervals for review after their training is completed. Preliminary lectures on shock and treatment of open wounds have also been presented.

Classes are being organized in maxillofacial surgery, oral surgery, serology, taking of blood for transfusion and in the treatment of shock, hemorrhage and open wounds.

Dr. Ralph Christy, president of the state dental association, in a report to the Dental Preparedness Committee of the American Dental Association, emphasized the desire of dentists to assist the medical profession in an emergency, the willingness of physicians to give the necessary instruction and the importance of practical training in hospitals in addition to didactic lectures.

The Medical Division of the Office of Civilian Defense in April issued a statement recommending that dentists qualify themselves in first aid in order that they may act as instructors and as members of emergency medical field units in casualty stations and first aid posts in the event of air raids, in the administration of anesthesia and in the care of injuries of the face and jaws.

ORGANIZATION SECTION

OFFICIAL NOTES

GRANTS AVAILABLE FOR RESEARCH

The Committee on Scientific Research of the American Medical Association invites applications for grants of money to aid in research on problems bearing more or less directly on clinical

medicine. Preference is given to requests for moderate amounts to meet specific needs. Application forms may be obtained from the Committee on Scientific Research at 535 North Dearborn Street, Chicago.

MEDICAL LEGISLATION

DISTRICT OF COLUMBIA

Change in Status—S 2804, proposing to define the real property exempt from taxation in the District of Columbia, has been recommitted to the Senate Committee on the District of Columbia and has been rereported by that committee, with additional amendments. As rereported, the bill specifically exempts from taxation buildings belonging to and used in carrying on the purposes and activities of the Medical Society of the District of Columbia.

MEDICAL BILLS IN CONGRESS

Changes in Status—H R 7378, the Revenue Act of 1942, has passed the House and Senate. As passed by the Senate the bill retains the House provision providing relief to the estate of a taxpayer in connection with the uncollected accounts on the books of the taxpayer at the time of death. A Senate amendment, if concurred in by the House, will permit the deduction of expenses incurred for medical care when in excess of 5 per cent of the taxpayer's income. The maximum deduction may not exceed \$2,500 in the case of the head of a family and not in excess of \$1,250 in case of all other individuals. H R 7164 has been signed by the President, amending the Soldiers' and Sailors' Civil Relief Act. Elsewhere in this issue appears an analysis of this new law. Of particular interest to physicians is the section authorizing the cancellation of leases on premises occupied for professional purposes. S 2248 has passed the House and Senate, providing for the care and custody of insane residents of Alaska. S 2676 has passed the House and Senate, providing for medical care and funeral expenses for certain members of the Naval Reserve Officers' Training Corps. H R 6839 has been reported to the House, providing for the appointment in the Naval and Marine Corps Reserve of persons with physical disabilities. H R 7311 has passed the House, proposing to grant domiciliary care and medical and hospital treatment to veterans of World War II on a parity with veterans of other

wars. The House Committee on Ways and Means has ordered reported H R 7568, relating to the manufacture and distribution of narcotic drugs. H R 7661 has been reported to the House, providing for the rehabilitation of disabled veterans of the present war.

Bills Introduced—S 2820, introduced by Senator Johnson, Colorado, H R 7633, introduced by Representative Edmiston, West Virginia, and H R 7678, introduced by Representative Jonkman, Michigan, propose to increase the pay and allowances of members of the Army Nurse Corps. S 2827, introduced by Senator Walsh, Massachusetts, for himself and Senator Clark, Missouri, proposes to provide for the rehabilitation of disabled veterans of the present war. S 2832 and S 2833, introduced by Senator Clark, Missouri, propose to extend the provisions of existing law regarding hospital and medical care to veterans to any officer, enlisted man, member of the Army Nurse Corps (female) or Navy Nurse Corps (female) employed in the active military or naval service of the United States on or after Dec 7, 1941 and before the termination of the present war. The latter bill provides that in granting hospital treatment and domiciliary care where such treatment or care is for disabilities not shown to be due to military or naval service the Administrator of Veterans Affairs is authorized and directed to give preference to veterans who have been discharged by reason of disability and to veterans entitled to or receiving compensation, pension or retirement pay for service connected disabilities. H R 7634 and H R 7662 introduced by Representative Rankin, Mississippi, provide for vocational rehabilitation and the return to civil employment of certain persons disabled under circumstances entitling them after discharge or separation from the military or naval forces to a pension or retirement pay. H R 7673, introduced by Representative Rogers, Massachusetts, provides that active duty as a member of the Women's Army Auxiliary Corps shall be considered as active military service for the purpose of medical and hospital treatment and domiciliary care under laws administered by the Veterans Administration.

WOMAN'S AUXILIARY

New Jersey

A Reciprocity Tea was held by the Gloucester County auxiliary in Woodbury recently. Fifty members and guests were present, representing several parent teacher associations and women's clubs of the county.

At the May meeting of the Hudson County auxiliary in Jersey City, Mrs. Arthur Largay, former president, showed a picture of the canteen that the auxiliary purchased and gave to the British War Relief Society. A letter was received, from which she read the following: "This is an appreciative line to inform you of the splendid work that has been performed by your up to date Canteen bearing the inscription Presented by the Woman's Auxiliary, Hudson County Medical Society, Jersey City, New Jersey U S A, now stationed near London. The Vehicle has done good work, such as serving food to demolition workers making trips to isolated anti-aircraft, observation and balloon barrage squads and small camps. When raids occur,

whether small or great, Salvation Army canteens rush to the scene. Responsible authorities also greatly appreciate the timely work that these canteens perform and the kindness and sacrifice which has made them possible."

Texas

The Southwest District auxiliary was organized June 26 at Kerrville. Twenty-four women were present and both the Fifth and the Sixth District were well represented. Mrs. P. R. Denman Houston, state president, assisted. Mrs. S. E. Thompson of Kerrville was elected Council Woman for the Fifth and Sixth districts.

After the meeting a barbecue supper was served at the home of Dr. and Mrs. Thompson. On June 27 Mrs. Walter A. Minshel and Mrs. H. H. Gallatin of Kerrville complimented Mrs. Denman with a breakfast on the lawn of the Gallatin home. A large group from several auxiliaries in the Southwest District attended.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

New Chief of Child Hygiene—Dr Jessie M Bierman, regional consultant in maternal and child hygiene, U S Children's Bureau, has been appointed chief of the bureau of child hygiene of the California State Department of Health, San Francisco. She succeeds Dr Ellen S Strdtmuller. Dr Bierman, who graduated at Rusli Medical College in 1927, has served as director of the child welfare division of the Montana State Department of Public Health and assistant director of the division of maternal and child hygiene of the Children's Bureau.

Laboratory of Electroencephalography—A new laboratory of electroencephalography has been opened at Stanford University School of Medicine, San Francisco. The new instrument has been under construction and adjustment for nearly ten months. At present the new laboratory is being used part of each day for testing by the military services. According to the announcement, the electroencephalograph just completed is unique among such apparatus in that it is entirely remotely controlled, thus avoiding electrical interference. It holds a newly invented automatic calibrating device to give instant interpretation of the currents being recorded. The apparatus consists of four sets of amplifiers housed within a single unit. The Irwin Foundation, San Francisco, has supported the project.

COLORADO

The Annual Friedman Lectures—The third annual Friedman Lectures and Conferences, given under the auspices of the National Jewish Hospital in cooperation with the Medical Society of the City and County of Denver and the University of Colorado School of Medicine, will be given in Denver November 2-4. On Monday evening November 2, at a joint meeting of the school of medicine and the hospital, Col John L Kantor, New York, will discuss "Digestive Symptoms in the Tuberculous and Their Management" and Major Richard H Meade Jr, Denver, "Extrapleural and Extrapariosteal Pneumony in the Treatment of Pulmonary Tuberculosis." At a joint session of the medical school and society Tuesday evening Colonel Kantor will speak on "Roentgen Study of the Digestive Tract in the Tuberculous," and Major Meade "Management of War Injuries of the Chest." Clinical sessions will be conducted by both speakers on Tuesday and Wednesday.

ILLINOIS

Personal—Dr Robert C Farrner, director of the East Side Health District, East St Louis has been appointed defense zone health officer for St Clair County, Dr Nordahl O Gunderson, Rockford, of Winnebago County, and Dr Sumner M Miller, Peoria, of Peoria County. —Dr Frederick L Eidl Moline, has been named school physician of Augustana College for the duration of the war, succeeding Dr Joseph G Gustafson, Moline, who has entered army service.

Chicago

Lecture on Genetic Variation in Plant Pathogens—Elvin C Stakman, PhD, St Paul, chief of the division of plant pathology and botany, University of Minnesota and pathologist and agent, U S Department of Agriculture, will deliver an illustrated lecture on "Genetic Variation in Plant Pathogens and Its Practical Importance" at a joint meeting of the Institute of Medicine of Chicago and the Chicago Society of Internal Medicine, October 23 at the Palmer House.

Grant for Study of Renal Hypertension—The John and Mary R Markle Foundation has authorized a grant-in-aid of \$7,000 over a two year period for the support of the research in experimental renal hypertension in progress at the University of Illinois College of Medicine. The work is under the direction of Dr George Wakerlin, professor and head of the department of physiology. Clarence A Johnson, PhD, assistant professor in physiological chemistry, Edwin L Smith, PhD, instructor in physiology, and others are associated in the investigation.

Research Fellowships Available—Applications for research fellowships in medicine, dentistry and pharmacy in the University of Illinois are now being considered for the year beginning Sept 1, 1943. Appointments to these fellowships will be

announced on January 1. Candidates must have completed a training of not less than eight years beyond high school graduation. The fellowship carries a stipend of \$1,200 each calendar year with one month's vacation. Application blanks may be secured from the Secretary of the Committee on Graduate Work in Medicine, Dentistry and Pharmacy, 1853 West Polk Street.

IOWA

Anesthesia Society Proposed—A group of physicians recently met at the University Hospitals, Iowa City, to discuss the formation of an Iowa Anesthesiological Society. Before plans are completed for a permanent organization, an attempt is being made to learn the extent of interest of the physicians in the state doing this specialty. Dr Stuart C Cullen, anesthesia division, University Hospitals, Iowa City, is accepting comments from physicians throughout the state who are practicing anesthesia either part time or full time.

Immunization Program Expanded to Include Diphtheria—The week of November 9 has been set aside by the state medical society for its annual program of vaccination against smallpox. This year the project has been expanded to include immunization against diphtheria. The state department of health will furnish without cost the preventive agents for the program. It will also arrange payment of carrying charge to local druggists appointed by the county medical society to handle and dispense immunizing agents furnished by the department. This payment will be on the basis of 10 per cent of the cost to the state. The educational features of the program will be worked out in cooperation with local agencies throughout the state.

MINNESOTA

Dr Fishbein to Lecture in St Paul and Minneapolis—Dr Morris Fishbein, Chicago, Editor of THE JOURNAL, will fill a number of speaking engagements in St Paul and Minneapolis on October 29-30 under the auspices of the Minnesota Public Health Association. He will address the general session and two sectional meetings of the Minnesota Education Association at the Minneapolis Auditorium. Dr Fishbein will be the principal speaker at the annual session of the Minnesota Public Health Association in Minneapolis on October 30. On October 29 he will address a group of Christmas Seal volunteer publicity workers in St Paul. A banquet is planned in his honor at the Nicollet Hotel on October 29.

MISSOURI

County Health Forum—On October 21 Dr Hiram Winnett Orr, Lincoln, Neb., will open the annual Jackson County Health Forum with a talk on "Backache and Back Injuries." The forum is sponsored by the auxiliaries of all the accredited hospitals of Jackson County. Other lectures in the series will be

Dr Walter C Alvarez, Rochester, Minn. November 18 Stomach Ulcers

Dr Morris Fishbein, Chicago January 20 Medicine and the War

Dr Karl A Menninger, Topeka Kan. February 17 Scientific Personality Study

Dr Clarence D Selby, Detroit March 17 Health Industry and Manpower

Dr Cyrus Sturgis, Ann Arbor Mich. April 21 Blood Transfusions Throughout the Ages Their Place in Modern Medicine

Area Industrial Hygiene Units Organized—A metropolitan St Louis Industrial Hygiene Service has been established to meet demands created by the expansion of war production industry in the area and to provide the residents of both county and city with the benefits of a good industrial hygiene program. The full resources of both city and county health departments are available to the metropolitan service under the administration of one director, and an advisory council consisting of the health commissioners and the directors of sanitation and nursing of each department. According to *Industrial Hygiene*, this is the first coordinated industrial hygiene service of its kind. The area served by the service is one of the most highly industrialized areas in the nation both from the peace time and war effort point of view. Mr Robert M Brown, formerly supervising engineer of the industrial hygiene service for the St Louis health department is the director of the unit which is a joint responsibility of the health commissioners of the city and county. The health departments of Kansas City Jackson and Clay counties have combined their industrial hygiene personnel to form the Kansas City Area Industrial Hygiene Service. The new unit has the authority to extend services to industry in this area without regard for city or county lines. H F Schulte is director and R A Carter is industrial hygiene engineer. The services of an industrial hygiene physician are available to the unit on a part time basis from the state board of health.

NEW JERSEY

Memorial to Dr Ill—The Academy of Medicine of Northern New Jersey held a memorial meeting October 15 in honor of the late Dr Edward J Ill, the academy's first president. A committee has been appointed to consider the creation of a suitable memorial to Dr Ill.

Survey to Determine Need of Child Care Program—A statewide study to determine the necessity of a child care program to aid mothers employed in war industries has been approved by the state board of education, newspapers reported, October 4. Charles H Elliott, Ph D, commissioner of education for the state, has been authorized to appoint a supervisor. Dr Elliott, in a statement to the press, stated that there was a general feeling in Washington that women with children younger than 14 years should remain at home and let childless married women fill jobs in war plants, thus releasing their husbands for combat duty.

NEW YORK

Use of Sulfadiazine Discontinued—Sulfadiazine will no longer be furnished to laboratory supply stations throughout the state for the treatment of pneumococcal infections. The decision was reached by the state department of health in view of the opinion of experts that sulfadiazine does not combat the pneumococcus any more effectively than sulfathiazole. When the present supply of sulfadiazine is exhausted, only sulfathiazole and sulfapyridine will be furnished to the supply stations for the treatment of pneumococcal infections. Reports of toxic reactions, particularly renal reactions, complicating its use have appeared with increasing frequency in the literature, *Health News* reports.

New York City

Latin American Chosen as Salmon Lecturer—Dr Emilio Mira professor of psychiatry at the University of Buenos Aires, Argentina, and formerly full professor of psychiatry at the University of Barcelona, Spain, has been announced as the Salmon Lecturer for 1942, according to the Salmon Committee on Psychiatry and Mental Hygiene of the New York Academy of Medicine. The lectures will be held on three successive Friday evenings November 6, 13 and 20, in the New York Academy of Medicine Building. The Salmon committee each year selects an outstanding specialist in psychiatry, neurology or mental hygiene to deliver the series of lectures. Dr Mira will discuss "Psychiatry at War." In his first lecture he will discuss the psychopathology of fear and anger reactions in wartime, in his second lecture he will discuss the duties of the psychiatrist in wartime and his personal experiences in the Spanish War, and in his third lecture November 13, Dr Mira will cover new techniques for detecting and controlling "fighting power" in individuals and armies. According to the announcement, in connection with the third lecture on the determination of fighting power, Dr Mira has originated a new psychological test. The new test has already been applied successfully in England and in Argentina. Dr Mira received his license in medicine from the University of Barcelona and his medical degree from the Central University in Madrid. He held three full professorships at the University of Barcelona—on the faculty of philosophy, the faculty of economic and social sciences and the faculty of medicine.

NORTH CAROLINA

Highway Marker Honors Physician—A state highway marker was recently unveiled in honor of the late Dr Solomon S Satchwell, founder of the Medical Society of the State of North Carolina and the first president of the state board of health. T T Murphy, secretary of the Pender County Board of Health presented the marker on behalf of the county and of the state of North Carolina to a group of relatives of the late Dr Satchwell. The marker was unveiled by four grandchildren of the physician. Dr Satchwell was born in Beaufort County Oct 26, 1821 and died at his home at Burgaw, Oct 9, 1892. He graduated at the University of New York in 1850. In 1861 he entered the Confederate Army as the surgeon of the Twenty-Fifth North Carolina Regiment. At the end of the war in 1865 he returned to private practice at Burgaw. Dr Satchwell was one of the organizers of the North Carolina Medical Society in 1849. He served as president in 1868 and as secretary from 1854 to 1856. He was instrumental in promoting the organization of the state board of medical examiners and served for from 1866 to 1872 as a member. The law of 1877 created the state board of health and designated the state medical society as the constituted board. The medical

society met later to set up the board and appoint a committee to carry on the work. Dr Satchwell was made chairman and continued as such until 1879, when the board was reorganized by the legislature to include nine members. He served as a member of the board from 1879 to 1885 and as president in 1879, 1880 and 1881.

OHIO

Dr Lavan Joins Infantile Paralysis Foundation—Dr John L Lavan, health commissioner of Toledo and director of health service in Toledo schools, has resigned to become director of scientific research for the National Foundation of Infantile Paralysis, New York, effective October 1. Dr Lavan, who graduated at the University of Michigan Medical School, Ann Arbor, in 1914, served as health commissioner of Toledo from 1930 to 1931 and as director of public health and welfare at Kalamazoo, Mich, from 1932 to 1935. From 1935 until his recent return to Toledo, Dr Lavan has been health commissioner of Grand Rapids, Mich.

Resolution Concerning Practice of Physicians in Military Service—The council of the Ohio State Medical Association in regular session, September 20, adopted a resolution and recommendations for the consideration of all county medical societies urging steps to guarantee restoration of practice and positions vacated by physicians entering military service. The resolution also recommended that the various committees on medical preparedness or a special committee be designated to work out all details and to administer the mechanics of protecting the status of men entering the service as set forth in the resolution. The council also instructed the committee on education of the state medical society to initiate preliminary plans in cooperation with the medical schools of Cincinnati, Western Reserve and Ohio State universities, for establishing refresher courses for the benefit of Ohio physicians when discharged from military service at the conclusion of the war, without cost to the physicians if such arrangement is feasible. The council also approved the display of a card in physicians' offices reminding patients of military services of their physicians and urging them to resume relationships on their return.

PENNSYLVANIA

War Benevolence Fund—The Cambria County Medical Society adopted a resolution at its September meeting asking for the establishment of a war benevolence fund for the benefit of its members who are in active military service. The resolution calls for the contribution of \$25 a month by all members who remain out of military service and in active practice, the fund to be distributed equitably among members of the society who are in active service. The fund would also be available to families of men in the service in case of need. The resolution also carried further stipulations as to the type of investment and the manner of administration of the fund. It was also provided that all expenses incident to the fund would be paid by the county medical society.

Philadelphia

Lectures for Medical Officers by College of Physicians—A series of postgraduate lectures has been arranged by the American College of Physicians for medical officers of the armed forces, physicians anticipating early entry on active duty and members of the college. The lectures will be given at the U S Naval Hospital, October 20-22. The evening sessions will be devoted to consideration of gastrointestinal problems, blood studies and some of the medical aspects of trauma. The speakers will be:

- Dr Henry L Bockus: A Classification of Chronic Diarrhea
- Dr Charles L Brown: Recent Advances in Our Knowledge of Small Bowel Diseases
- Dr Joseph C Yaskin: Functional Gastrointestinal Disturbances
- Dr Harrison I Lippin: Toxic Effects of the Sulfonamides on the Blood
- Dr W Harding Kneeder: Importance of Blood Examination in Certain Tropical Diseases
- Dr George E Farrar Jr: Management of Purpura
- Dr Walter E Lee: Crush Syndrome and Burns
- Dr Jonathan E Rhoads: Problems of Fluid Balance in the Traumatized Patient
- Dr Max M Strumia: Post Transfusion Reactions (Blood Serum and Plasma)

The following lectures have been arranged by the college for the fifth annual 'round up' for fellows and associates of the college, October 23, to be given at 4200 Pine Street:

- Dr Edmund C Boots: Pittsburgh Thirty Five Millimeter Films in the Diagnosis of Chest Conditions
- Dr Ferdinand Fetter: Carcinoma of the Lung
- Dr Williams S McCann: Rochester N Y Management of Liver Disease
- Dr Gordon B Tayloe: Fever Therapy
- Dr Victor W Logan: New York Peptic Ulcer in the U S Navy
- Dr Frederic H Lewey: Neurotic Reaction in War

GENERAL

National Safety Congress—The annual National Safety Congress and Exposition of the National Safety Council will be held at the Hotel Sherman, Chicago, October 27-29. The program will include sessions in air raid precautions for industry, dusts, fumes, gases and vapors, fire safety in war plants, fundamental causes of accidents, gas and electric welding, industrial health, occupational diseases in munitions manufacture, safety engineering exchange, safety in foremanship and war safety problems. Included among the speakers for the session on industrial health are:

Dr. Edward C. Holmblad, Chicago: Industrial Rehabilitation of Permanently Injured Workers
Dr. Harvey Battle, Philadelphia: Strains and Hernia
Dr. James H. Stierner, Rochester, N. Y.: Safe Use of Substitute Solvents and Chemicals
Dr. Frederick W. Slobe, Chicago: What the Industrial Nurse Needs to Know About Hand and Foot Injuries
Dr. Florence Magnus, Milwaukee: What the Industrial Nurse Can Do About Tuberculosis

Shortage of Suitable Sheep Intestines for Sutures—Sheepmen of the United States can and surgeons in war zones and at home by use of Leaflet No. 228 just prepared by Merriett P. Sarges, Sc.D., and Aurel O. Foster, Sc.D., of the bureau of animal industry, the U. S. Department of Agriculture announced September 30. Copies of the leaflet, "Nodular Worm Disease of Sheep," may be obtained free from the bureau of animal industry, Agricultural Research Administration, U. S. Department of Agriculture, Washington, D. C. There is a serious shortage in the supply of suitable sheep intestines needed in the manufacture of high quality, absorbible sutures used by surgeons in closing wounds and as ligatures. Casings suitable for the production of surgical sutures must be from sheep free from nodular worms, a common internal parasite. The worms are responsible for thickened or nodular condition in the intestines which makes them unfit for surgical sutures. Worm infestations are readily preventable by treating the sheep with the drug phenothiazine, given in the feed in capsules, or in a drench under the supervision of a veterinarian.

Meeting of Life Insurance Medical Directors—The fifty-third annual meeting of the Association of Life Insurance Medical Directors of America will be held at the Hotel Pennsylvania, Philadelphia, October 21-22 under the presidency of Dr. David E. W. Wenstrand, Milwaukee. The speakers will include:

Dr. Earl C. Bonnett and Mr. Edward A. Lew, New York: A Mortality Study of Systolic Murmurs
Col. Eugen I. G. Reinartz, Randolph Field, Texas: Effect of Flight on Man
Drs. Ernest J. Dewees and Paul H. Langner, Jr., Philadelphia: A Study of Glucose Tolerance Tests and the Significance of Glycosuria
Dr. Gilbert Horrax, Boston: Criteria of Prognosis After Head Injuries with Respect to Longevity and Dishability
Dr. Olin M. Eakins, Pittsburgh: Breaking the Rule of Thumb
Dr. Frank N. Wilson, Ann Arbor: The Precordial Electrocardiogram
Drs. Wenstrand and Gamber, F. Tegmeyer, Milwaukee: Significance of Small Numbers of Red and White Blood Cells in the Urine
Dr. Meredith F. Campbell, New York: Prognostic Considerations of Hematuria and Pyuria
Lieut. Col. John Keith Gordon, Montreal: Experiences with the Canadian Army in England
Dr. Edward A. Strecker, Philadelphia: Military Neuropsychiatric Disabilities and Their Treatment

Award for Vitamin B Research—Nominations are solicited for the 1943 award of \$1,000 established by Mead Johnson and Company to promote research dealing with the B complex vitamins. The recipient of this award will be chosen by a committee of judges of the American Institute of Nutrition, and the formal presentation will be made at the annual meeting of the institute at Cleveland on April 7, 1943. The award will be given to the laboratory (nonclinical) or clinical research worker in the United States or Canada who in the opinion of the judges, has published during the previous calendar year January 1 to December 31 the most meritorious scientific report dealing with the field of the B complex vitamins. While the award will be given primarily for publication of specific papers, the judges are given considerable latitude in the exercise of their function. Membership in the American Institute is not a requisite of eligibility for the award. The award may be given to a worker for valuable contributions over an extended period but not necessarily representative of a given year. To be considered by the committee of judges, nominations for this award for work published in 1942 must be in the hands of the secretary by Jan. 10, 1943. The nominations should be accompanied by such data relative to the nominee and his research as will facilitate the task of the committee of judges in its consideration of the nomination. Arthur H. Smith, Ph.D., Wayne University College of Medicine, Detroit, is secretary of the American Institute of Nutrition.

SPECIAL NEWS

(THIS NEWS WAS ASSEMBLED ESPECIALLY FOR USE IN THE JOURNAL)

Public Health Under Hitler's Rule—*Neues Wiener Tageblatt* of July 7 reports that in Bulgaria there are more than eight hundred medical posts vacant. In order to relieve this shortage of doctors it has been decided that one hundred and twenty medical students in their tenth and twelfth semesters, will be absolved from their last examination and will be allowed to carry on their first practical work in the provincial hospitals.

According to *Narodni Prace*, Prague, of July 7 the public health office of Budejovice announces that an x-ray ambulance train will come to Budejovice shortly which will be equipped with the most up to date x-ray apparatus and other appropriate instruments, also of the best kind. Specialists will examine free of charge any one interested, above all those who have been affected by some sort of lung disease.

Eleftheron Vima, Athens, of July 12 reports that the doctors and chemists of Salonika have met to study the health situation and to prevent profiteering in medicines. The meeting was attended by the German medical and health officers, who emphasized the help afforded by Germany by the release of substantial quantities of medicines and other medical supplies for the Greek wounded, hospitals and children, by cooperating in the anti-malarial campaign, by founding and expanding hospitals and by active assistance in the organization of hygienic services to combat epidemics. In the future German authorities would give the most careful attention to the Greek people. Importation of the best medicines from Germany would assure good treatment. A mixed commission is to superintend the distribution and to insure that there is no speculation. Speculators in medical supplies will receive the severest penalties.

Promos Typos, Athens, of July 9 in referring to the distribution of quinine, states that supplies will be distributed only to malaria patients who have a medical prescription countersigned by the police and with the name and address of the patient. The ration for a six day treatment (which is the maximum allowed) must not exceed three tubes containing thirty tablets. Doctors disobeying this rule will be severely punished, and the public is warned against counterfeit supplies not bearing the official packing.

Promos Typos, Athens, of July 9 reports that, according to an announcement by the government, there are now ample supplies of quinine but that it will be issued only on a doctor's prescription and in quantities for not more than six days.

Akropolis, Athens, of July 9 reports that chemists refuse to make up prescriptions for those customers who look poor and likely to be unable to pay the enormous prices for medicines, which have increased by 400 per cent in the last month.

According to the *Donauszettung* of July 12, 28,000 persons in eastern Slovakia have been inoculated against typhoid (bauchtyphus), which claims many victims each year. During March typhoid broke out in the Bartfeld district but immediate inoculation of 7,000 persons succeeded in localizing the epidemic. The government intends to subsidize the canalization works in order to improve the drinking water, which has hitherto been a frequent bearer of the disease.

Dnevnik, Sofia, of June 20 reports that cases of spotted typhus had risen to more than 200, but only 10 new cases had been discovered in the past week.

According to *Honvedorvos*, 1941 neurotic and mentally depressed members of the Hungarian army are sometimes guilty of self-inflicted injuries which include 'artificial trachoma', hernia, heart trouble induced by poisons, jaundice, gonorrhea, inflammation of the testicles by the action of nettles, edema of the limbs caused by tying braces round them, ulcers and infected wounds.

Dagens Nyheter, Stockholm, of July 14 reports that a number of cases of spotted fever have occurred among Russian prisoners in the Bodoe area. The whole area around the German fish factory A/S Frostflet, has been closed because of the danger of contagion. The first cases occurred shortly after the arrival at Bodoe on June 20 of eight hundred Russian prisoners, who are working there for the Germans. A few cases have also been reported from Mosjoen. The sugar ration for smokers will be reduced to 500 Gm a month, according to *Karjala*, Vnpuri, of August 21, however, nonsmokers will not obtain an extra sugar ration of 250 Gm when tobacco rationing starts. When the Ministry of Supply announced the choice between tobacco and sugar it was understood that nonsmokers would obtain an extra sugar ration of 250 Gm, if a misunderstanding existed at this time it was said to have been due to 'the clumsiness of the Supply Ministry.'

Famine in Europe

Food conditions in a large part of the European continent occupied by the Germans are deplorable. A famine relief committee formed by church leaders has collected evidence. In Greece famine was so severe that 320,000 deaths were registered from August 1941 to the end of March 1942, which amounted to five times the normal death rate. In December the average daily consumption of bread had been reduced from the normal 27 ounces to $2\frac{1}{2}$ ounces or less. In January 900 deaths daily from famine were reported. The children were most affected, and their resistance to an epidemic of diphtheria, which swept Athens and the Piraeus, was impaired. Some alleviation of the conditions in the Greek cities has taken place as a result of food shipments organized by the Allied governments.

In Belgium starvation edema has appeared and scurvy, rickets, anemia, skin diseases and eye disorders are becoming common. Two thirds of the school children get little breakfast and a third get an inadequate midday meal. In unoccupied France conditions are similar to those of 1918, infant mortality increased 45 per cent between 1939 and 1940. In occupied France a reasonable standard of living is possible only in the rural districts. In the House of Commons Mr. Dingle Foot, parliamentary secretary to the Ministry of Economic Warfare, stated that in occupied Europe the urban populations were living at a level below and in some cases substantially below, the standards of peacetime. In Belgium and France there had been during the past two years an increase in the incidence of certain diseases notably pneumonia and tuberculosis, for which an insufficient diet was no doubt one of the principal causes. By agreement with the British government, importation of food for the people in the blockaded area is allowed. Over the last thirteen months the Belgian government has purchased foodstuffs from the Portuguese. The British government would welcome the expansion of the scheme under which Belgian children, whose health has suffered, are sent to Switzerland, and is always willing to grant navicerts to the Swiss government to help to clothe and feed these children. It has also considered many schemes for what is called "controlled relief" in enemy occupied territories but found that they would all bring benefit, in some cases substantial, to the enemy.

In Poland the rations allowed are on a starvation level and the Jews get still less than the Poles. The British Famine Relief Committee, which includes every section of Christian and Jewish thought, is planning to send food and medical aid to occupied countries wherever this is possible. A German guaranty that it would not be used for the armies seems to have been observed. The American Friends Service Committee gives supplementary school meals to 85,000 children in unoccupied France and is supplementing feeding in refuge camps. A commission for Polish relief has been able to carry out controlled relief of 50,000 children.

Anemia and Leukopenia in X-Ray Workers

In the hospitals of the Emergency Medical Service (established for the treatment of war casualties) some workers in the x-ray department were taken off work because they were thought to be suffering from minor degrees of anemia due to the x-rays. But the director general of the service has declared this action unnecessary, as the anemia is almost certainly not due to the action of the rays. To allay uneasiness and as a

guide to the treatment of such cases he has issued the following note to all the hospitals of the Emergency Medical Service.

Periodic examination of x-ray workers has been carried out in many institutions for many years. In not one has a single case of aplastic anemia occurred, and there appears to be no record of it developing in any worker who was not also in contact with radium. A few cases of secondary anemia occur from time to time and appear to be due to the conditions of employment rather than to any specific action of the rays. Rare examples have been met in which the leukocyte count has been seriously reduced, but recovery has quickly followed short absence from work. An extremely rare example has been observed in King's College Hospital of a girl who, on return to work, developed severe leukopenia for the second time. She was advised to find some other occupation.

It is generally agreed that periodic blood examinations, at intervals of six to twelve months, are advisable for the detection of hemoglobin and red cell deficiencies in persons working under unfavorable surroundings, and of the very exceptional x-ray worker who may develop serious leukocyte deficiency. A blood examination of all candidates for employment in an x-ray department is a reasonable procedure. Minor degrees of anemia need not be treated more seriously in radiographers than in other occupations. Minor degrees of leukopenia should suggest further examination at short intervals, such as two weeks, and if confirmed and progressive should entail removal from work until the blood state is reestablished and the count found to remain constant. The term "x-ray anemia" has no particular meaning and should be avoided.

How the British Army Is Fed

At the War Department Laboratory, London, a demonstration was given of how scientific research has been harnessed to the task of feeding a great army. The services of a number of research organizations are used. These include the Department of Scientific and Industrial Research, the Directorate of Scientific Research, the Ministry of Supplies, the Scientific Adviser, the Ministry of Food, the Research Institute and the Medical Research Council. The organization to feed our armies is worldwide. It is run by business men from civil life, who may be described as "experts in khaki," and by administrative staff officers who combine a knowledge of army needs with a wide knowledge of organization and of those parts of the world where troops are stationed. During training the soldier is given the fullest and most varied ration which war conditions in Britain permit. Increased allowances of nationally rationed foods are given to build up his physique to withstand the strain of hard training and to prepare him for the greater strain of war. For active service the ration must be adequate, yet limited in weight, palatable, sustaining and immediately ready to eat after months of storage. For the armored fighting vehicle there is a ration designed to be carried in the mess tin and yet adequate to sustain a man for forty-eight hours. For a man fighting in the arctic regions there is a special ration. There is an emergency ration for a man who for a time is cut off from supplies. It consists of cocoa powder, milk protein, cocoa butter and icing sugar. For the extraordinary variety of peoples now incorporated in the British army—Sinhalese, Gurkhas, Moslems, Hindus, Czechs, Poles, Syrians, French, Yugoslavs, Kaffirs and others—there are special ration scales to meet their requirements. From the Middle East reports have recently been received showing complete satisfaction with the ration.

At the demonstration, samples of German rations captured in Libya were displayed. The British samples compared favorably with them. The British are more palatable, and analyses have shown that in the process of dehydration the Germans have failed to retain vitamin C. One of the few things in their ration which is not ersatz is the German sausage. The soup made from their powder is less attractive than that supplied to

the British soldier. Their rye bread and biscuit do not compare with those provided for our men. What was called "the dog biscuit" of the last war has gone forever. The biscuit we now supply contains more sugar and fat, has a high calory value and keeps for a good time. Plum and apple jam are no more. We now give a variety of jams—gooseberry, raspberry, black currant, mixed fruits and marmalade. Pills which the Germans claim give "pep" to their panzer troops have been taken from soldiers captured in the Middle East and analyzed. They consist of a low grade sugar and are not equal to the boiled sweets which form part of the British soldier's ration.

Other things shown at the demonstration included a powder consisting of tea, sugar and milk, from which tea can be made direct, and an emergency ration which looked like a bar of chocolate and, while weighing only 6 ounces, gives 800 calories of energy. For the troops overseas one hundred and thirty different ration scales have to be supplied. Almost forty of these are for the Middle East alone. Dehydrated products, some of which are still in the experimental stage, were shown. These will be of great value for places like Gibraltar but are of little value for desert warfare. Canned vegetables and meat are much better. One myth was exploded. There is no method of feeding men on tablets. Moisture and bulk are an essential part of human diet. But everything possible has been done to compress a satisfying day's food into the smallest space possible. So far the health of our army has been better than it has ever been in peacetime. There has been no case of dietetic deficiency.

The British Figure Improves with Rationing

Under our rationing system every one has enough food for the maintenance of health but most of us have much less than what we would like to eat of many important foods, such as meat, butter, sugar and eggs. Addressing a meeting, Lord Woolton, minister of food said that, while the stocks in this country of food were still considerably greater than at the outbreak of war, a time might come when it would be necessary for us to have still less meat. He appealed to people to eat more potatoes and blamed the slimming craze of a few years ago for the fall in the consumption of potatoes, because people said that they were fattening. He added 'Of course they were, when you had as much butter, sugar and sweets as you wanted. Now I have helped you. I have come to the rescue of the feminine figure. You cannot get fat on your diet now. Don't worry about getting fat, don't worry about your figure. The government is looking after that for you. They have taken away your petrol, so that you will have much more exercise. We have done everything that a reasonable government can do to look after the human form divine."

Honorary Fellowship of Royal Society of Medicine

Eleven distinguished members of the profession, representing Britain, the dominions and the United States have been elected to the honorary fellowship of the Royal Society of Medicine. The two British ones are Lord Horder and Sir John Herbert Parsons (ophthalmologist), a former president of the society. From Canada there are Prof W. E. Gallie, dean of the Medical Faculty of the University of Toronto, and Prof Jonathan Meakins, director of the Department of Medicine, McGill University. From Australia there are Sir Charles Blackburn, consulting physician, Royal Prince Alfred Hospital, Sydney, and Sir Hugh Devine, lecturer in surgery, University of Melbourne. New Zealand is represented by Sir Henry Lindo, professor of ophthalmology and dean of the medical faculty, Otago University, and South Africa by Dr A. W. Falconer, professor of medicine, University of Capetown. From the United States there are Dr Hugh Cabot, consulting surgeon, Mayo Clinic, Dr David Cheever, associate professor of surgical anatomy, Harvard (who had charge of the Harvard Surgical Unit in the last war), and Dr W. T. Longcope, physician in chief, Johns Hopkins Hospital.

BUENOS AIRES

(From Our Regular Correspondent)

Sept 5, 1942

Public Health in Chile

No epidemics have occurred since 1939 in Chile, according to official reports, with the exception of some cases of exanthematic typhus, which were immediately controlled. The efforts to control malaria in the northern parts of the country have given good results. The mortality in early childhood was exceedingly high (THE JOURNAL, Jan 10, 1942, p 159) but the feeding of mothers and children has been given much attention of late and in a short time the general condition of mothers and children should improve. Negotiations are under way for extending to the whole family the benefits of insurance in the Caja de Seguro Obligatorio for medical care. Now only infants of an insured parent are given medical care by the insurance company. By the new plan 3,600 persons will have the right to ask for medical care under this insurance and 200,000 or more children, who at present have no medical care. The administration of rations in public government restaurants free of charge to poor families has improved the health of the people. In 1940, thirty public restaurants gave more than four million rations to more than 1,200,000 persons, and more than one and a half million rations of breakfast and lunch were given to school children.

Control of Venereal Diseases in Peru

Laws concerning the medical care of patients with venereal diseases were recently promulgated by the president of Peru. A national department against venereal diseases was recently established with headquarters in Lima. Treatment of venereal diseases in the period of contagion is obligatory. If the patients are minors or mentally deficient, the parents are responsible for their treatment. Drugs for the treatment of venereal diseases are now sold only on medical prescriptions. Specific medicines against venereal diseases and treatment by correspondence are prohibited. Wet nurses must have a certificate of health. These medical certificates are given without any charge in the dispensaries and hospitals of the city. They are good only for three months, when a new one is required. Five per cent of the total number of beds in hospitals of public aid are going to be reserved for patients with venereal diseases.

Crusade Against Coca in Colombia

The minister of hygiene and social aid of Colombia recently promulgated a law by which the cultivation of Erythroxylon coca and its varieties are regulated by the government. A census will be made in the next four months in which the name of the owners of coca plantations, the number of trees, the size of the fields, the amount of coca harvested every year and the form in which coca leaves are sold will be recorded. The sale of coca leaves then will be prohibited unless the owners obtain a license from the authorities. One month after the publication of the law, no new plantations of coca will be permitted. The plantations on national or municipal property are to be immediately destroyed by the authorities.

Pan American Congress of Endocrinology

A conference was recently held with Dr. Bernardo A. Houssay as chairman for the appointment of an executive committee of the third Pan American Congress of Endocrinology, which will be held in Buenos Aires July 1-6, 1943. The official topics will be (1) endocrine factors of diabetes, (2) gonadotropins and (3) the adrenal cortex. There will also be several lectures on endocrinology. The official headquarters of the executive committee of the congress is the Instituto de Fisiologia de la Facultad de Ciencias Medicas of Buenos Aires, Calle Cordoba 2122. Letters requesting information should be sent to Eduardo Braun Menendez, the secretary of the congress, at that address.

Deaths

Samuel Bates Grubbs * Medical Director, U S Public Health Service, retired, Carmel, Ind., Columbia University College of Physicians and Surgeons, New York, 1896, became associated with the U S Public Health Service in 1897 and continued in that work until 1933, served as chief quarantine officer of the Panama Canal Zone in 1919-1920, sanitary inspector for the U S Army port of embarkation, New York, 1917-1918, health officer for the port of New York from 1921 to 1925, chief of the foreign quarantine division from 1925 to 1927, director of the Great Lakes district during 1928 and the next year served as adviser to the Los Angeles health department, chief quarantine officer for the Hawaiian Islands from 1929 to 1933, veteran of the Spanish American War and World War I, originated the vacuum cyande method of disinfecting clothing and rat proofing ships and the chopis index for bubonic plague, aged 71, died September 19, in Poughkeepsie, N Y, of coronary thrombosis.

Frank Vinsonhaler, Little Rock, Ark., College of Physicians and Surgeons, New York, 1885, dean from 1927 to 1939 and since then emeritus dean, appointed professor of ophthalmology, otology, rhinology and laryngology in 1893, and since 1932 professor of medical history and ethics at the University of Arkansas School of Medicine, member and past president of the Arkansas Medical Society and the Pulaski County Medical Society, member of the American Academy of Ophthalmology and Otolaryngology, fellow of the American College of Surgeons, served as a commander of a base hospital in France during World War I, formerly a colonel in the medical officers' reserve corps, specialist certified by the American Board of Ophthalmology, in 1935 was awarded a medal by Columbia University, New York, for conspicuous service rendered to the university, aged 78, died, September 1, of pneumonia.

William Forsyth Milroy, Los Angeles, College of Physicians and Surgeons, New York, 1883, formerly professor emeritus of clinical medicine at the University of Nebraska College of Medicine, Omaha, past president of the Nebraska State Medical Association and the Douglas County Medical Society, fellow of the American College of Physicians, at one time on the staffs of the Immanuel, Douglas County, Clarkson Memorial and the University of Nebraska hospitals, Omaha, discoverer of Milroy's disease, aged 86, died, September 21, of cardiac decompensation and cerebral artery thrombosis.

Montgomery Hunt Sicard, Westerville, N Y., Columbia University College of Physicians and Surgeons, New York, 1898, member of the Medical Society of the State of New York, formerly instructor of physical diagnosis at Cornell University Medical College, New York, aged 70, died September 22, in a hospital at Utica of cerebral thrombosis and arteriosclerosis.

William Warren Southwick * Marshalltown, Iowa, Chicago College of Medicine and Surgery, 1913, past president of the Marshall County Medical Society, formerly county coroner, aged 55, secretary and past president of the medical staff of the Evangelical Deaconess Home and Hospital, where he died, September 14, of ruptured duodenal ulcer and uremia.

Richard Lambert Shea, North Scituate, R I., Keokuk (Iowa) Medical College, 1894, formerly served as medical examiner of Scituate at one time first assistant physician at the Eastern Indiana Hospital for Insane, Richmond, aged 72, died, September 5, in the Rhode Island Hospital, Providence, of hypertensive cardiovascular disease and bronchopneumonia.

Harold Glover Horton, Saltville, Pa., Medico Chirurgien College of Philadelphia, 1912, member of the Medical Society of the State of Pennsylvania, past president of the Huntingdon County Medical Society, served as a member of the board of education, aged 55, died, September 2, in the J C Blair Memorial Hospital, Huntingdon, of coronary thrombosis.

Armand Ernest Larose, South Ryegate, Vt., School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, Que., Canada, 1916, chief surgeon of the Women's Hospital, Montreal, from 1929 to 1937, aged 51, died, August 21, in the Grace Dart Hospital, Montreal, of pulmonary tuberculosis.

Edward J Farnum, Fort Meyers, Fla., Bennett College of Eclectic Medicine and Surgery, Chicago 1889, became emeritus professor of the practice of surgery at his alma mater in 1906, at one time a member of the consulting staff of the Cook County Institutions at Dunming, aged 81, died, August 29, of coronary thrombosis.

John Laurence O'Toole, Haverhill, Mass., Tufts College Medical School, Boston, 1908, medical examiner of the fourth district of Essex County, formerly served as a member of the city board of health and board of education, aged 64, on the staff of the Hale Hospital, where he died, September 2, of coronary thrombosis.

Luigi Saverio Michela, Paterson, N J., Regia Università di Torino Facoltà di Medicina e Chirurgia, Italy, 1900, member of the Medical Society of New Jersey, served during World War I attending obstetrician on the staff of St Joseph's Hospital, aged 66, died, August 21, of acute myocarditis.

Thomas Tilden Norris, Krebs, Okla., University of Nashville (Tenn.) Medical Department, 1901, member of the Oklahoma State Medical Association, assistant physician of the Central Oklahoma State Hospital Annex, McAlester, since Sept. 1, 1939, aged 65, died, September 6, of cholangitis.

Ernest Day Everett, Lakeview, Ore., George Washington University School of Medicine, Washington, D C, 1908, member of the Oregon State Medical Society, at one time physician in the Indian Service, on the staff of the Lakeview Hospital, aged 64, died August 16, of aortic stenosis.

William James Cochran, Natick, Mass., Harvard Medical School, Boston 1887, member of the Massachusetts Medical Society, formerly chairman of the board of health of Natick, aged 80, a trustee of the Leonard Morse Hospital, where he died August 29, of arteriosclerotic heart disease.

William Kirk East * Atchison, Kan., John A Creighton Medical College, Omaha, 1914, past president of the Atchison County Medical Society, served as city and county health officer, past president of the staff of the Atchison Hospital, aged 53, died August 31, of coronary occlusion.

William Homer Axford * Chester, N J., University of Pennsylvania Department of Medicine, Philadelphia, 1901, at one time mayor of Bryn Mawr, formerly on the staff of the Bryn Mawr (N J) Hospital, aged 68, died, September 16, in St. Petersburg, Fla., of coronary occlusion.

Harry Edmond Downs, Alexandria, La., Medical Department of Tulane University of Louisiana, New Orleans 1902, veteran of the Spanish-American War, aged 71, died, September 9, in the Veterans Administration Facility of hypertensive and arteriosclerotic heart disease.

Oscar Anderson * Santa Monica, Calif., Dunham Medical College, Chicago 1902, served in the medical corps of the U S Army during World War I, aged 68, died, September 6, in a hospital at Long Beach of injuries received when struck by an automobile as he was crossing the street.

Irwin Seth Walker, Rangoon, Burma, College of Medical Evangelists, Los Angeles, 1937, L R C P, L R C S, Edinburgh, and L R I P & S, Glasgow 1938, associated with the American Seventh Day Adventist Mission, aged 34, died, August 4, in Bombay, India, of spinal meningitis.

Albert Alexander Roth * Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905, formerly member of the city board of health, aged 67, died August 27, in the Presbyterian Hospital of papillary carcinoma of the bladder.

George Robert Reinhold Hertzberg * Stamford Conn., Dartmouth Medical School, Hanover, N H, 1899, fellow of the American College of Surgeons, aged 68, on the staff of the Stamford Hospital, where he died, September 17, of carcinoma of the pancreas.

Charles Reed, Towanda, Pa., Jefferson Medical College of Philadelphia 1880, member of the Medical Society of the State of Pennsylvania, for many years examiner for the U S Pension board, aged 85, died suddenly, September 4, of coronary thrombosis.

Samuel Early Centerfit, Montgomery, Ala., New York University Medical College, New York 1898, member of the Medical Association of the State of Alabama, aged 68, died, September 1, in Birmingham of prostatic hypertrophy and pyonephrosis.

Samuel Claude Harrell Jr, Monrath, Texas, Vanderbilt University School of Medicine, Nashville, Tenn., 1937, member of the State Medical Association of Texas, aged 29, died, September 6, of injuries received in an automobile accident.

John Frampton Bryson, Girardville, Pa., Jefferson Medical College of Philadelphia 1903, county deputy coroner and bank president, aged 72, died, September 9, in the George F Geisinger Hospital, Danville, of coronary thrombosis.

Charles Clarence Rose, Oklahoma City, University of Louisville (Ky.) Medical Department, 1912, served during World War I, on the staff of the Southwest Medical Clinic, aged 52, died September 5, of coronary thrombosis.

Arthur E Wyman, Sabattus, Maine, Baltimore Medical College, 1906, aged 70, died recently in the Central Maine General Hospital, Lewiston, of injuries received when struck by an automobile as he was crossing the street

William Manning Tappan @ Holland, Mich, University of Michigan Medical School, Ann Arbor, 1916, health officer of Holland, on the staff of the Holland City Hospital, aged 53, died, September 12, of coronary thrombosis

Jacob Meyer Heyde, Loudonville, Ohio, Jefferson Medical College of Philadelphia, 1900, served during World War I, formerly member of the school board, aged 64, died, September 2, of cardiovascular disease

Norman Carl Reglien, Michigan City, Ind, University of Michigan Medical School, Ann Arbor, 1928, aged 39, on the staff of St Anthony Hospital, where he died, September 11, of myocardial infarction

Joseph Pawell Wimberley, Halifax, N C, Jefferson Medical College of Philadelphia, 1899, aged 65, died, August 14, in the Rocky Mount Sanitarium, Rocky Mount, of arteriosclerotic heart disease

Harry H Stretton, Ingleside, Neb, Cotner University Medical Department, Lincoln, 1895, assistant superintendent of the Hastings State Hospital, aged 75, died, September 7, of coronary thrombosis

Robert Pythian Hackley, Medaryville, Ind, Kentucky School of Medicine, Louisville, 1900, formerly served as county health officer, aged 71, died, August 30, of cerebral hemorrhage and arteriosclerosis

John Lovell Hanchette, Oakland, Calif, Chicago Homeopathic Medical College, 1889, formerly a member of the board of education of Sioux City, Iowa, aged 82, died, August 29, of pulmonary edema

John Larkin Walker, Hillsboro, Ohio, University of Cincinnati College of Medicine, 1931, member of the Ohio State Medical Association, aged 36, was found dead, September 12, of heart disease

Sterling S Brown @ Pleasant View, Ky, Hospital College of Medicine, Louisville, 1896, member of the Tennessee State Medical Association, aged 71, died, September 4, of heart block

Arthur Francis Daly @ Chicago, Loyola University School of Medicine, Chicago, 1922, on the staff of the Roseland Community Hospital, aged 47, died, September 13, of coronary thrombosis

James Dave Edmundson, Orland Calif, Missouri Medical College, St. Louis, 1888, past president of the Glenn County Medical Society, aged 85, died, August 21, of cardiac decompensation

David W Shellabarger, Potsdam, Ohio, Medical College of Ohio, Cincinnati, 1892, member of the Ohio State Medical Association, aged 74, died, August 18, of carcinoma of the prostate

Hugo Victor Pribyl @ Chicago, Rush Medical College, Chicago, 1899, on the staff of the Jackson Park Hospital, aged 71, was found dead, September 20, of a self inflicted bullet wound

Leopold Adler @ Detroit University of Kolozsvar Hungary, 1913, served on the staff of the Woman's Hospital, aged 59, died, August 17, of nephritis, uremia and cerebral thrombosis

George N Springer, Hohenwald, Tenn, Memphis Hospital Medical College, 1897, aged 74, died, August 30, in the King's Daughters Hospital, Columbia, of bronchopneumonia

Archie Tilden Gibson @ Morrisonville, Ill, Barnes Medical College, St. Louis, 1896, aged 69, died, September 9, in the Missouri Baptist Hospital, St. Louis, of cerebral hemorrhage

Joel Dixon Sturdevant @ Noblesville, Ind, Medical College of Indiana, Indianapolis, 1904, served during World War I, aged 64, died, August 31, of cirrhosis of the liver

John Franklin Mouton, Lafayette, La, College of Physicians and Surgeons, Baltimore, 1889, member of the Louisiana State Medical Society, aged 74, died, September 3

Lewis Cass White, Colorado Springs, Colo, College of Physicians and Surgeons, Keokuk, Iowa, 1892, aged 84, died, September 10, of cardiovascular renal disease

Neal Davidson Monger, San Benito, Texas, University of Texas School of Medicine, Galveston, 1922, aged 44, was found dead, August 19, of coronary thrombosis

Robert Lee Murph, Dyersburg, Tenn Kentucky School of Medicine, Louisville, 1891, aged 73, died, August 26 in St Joseph's Hospital, Memphis, of pellagra

Horace Wilbert Brown, Chattanooga, Tenn (licensed in Tennessee in 1902) aged 78, died, August 23, in Urbana, Ill, of cerebral hemorrhage and arteriosclerosis

Raphael Aredis G Constantian, New York University of Edinburgh Faculty of Medicine, Scotland, 1893, aged 71, died, September 10, of coronary occlusion

Thomas Edward Blackshear, Pensacola, Fla, University of Maryland School of Medicine, Baltimore, 1894, aged 71, died, September 7, of coronary occlusion

Hughes George Meaker @ Mansfield, Pa, Medical-Chirurgical College of Philadelphia, 1914, aged 56, died, August 21, of streptococcal pneumonia

Cornelis Schagen, Oakland, Calif, Universiteit van Amsterdam Geneeskunde Faculteit, Netherlands, 1901, aged 68, died, August 7, of coronary embolism

Marks Priestley Hine, Philadelphia, Jefferson Medical College of Philadelphia, 1888, also a druggist, aged 83, died, September 2, of heart disease

Joseph W Taylor, Huntsville, Mo, Jefferson Medical College of Philadelphia, 1878, aged 87, died, September 10, of carcinoma of the stomach

Martin Johnson Bartlett, Oklahoma City, Hospital College of Medicine, Louisville, Ky, 1906, aged 71, died, September 5, of heart disease

Rufus King Noyes, Boston, Dartmouth Medical School, Hanover, N H, 1875, aged 89, died, August 31, in Atkinson, N H, of myocarditis

Anson P Howland, Cleveland, Western Reserve University Medical Department, Cleveland, 1896, aged 72, died, August 28, of heart disease

James Christian Spiegel, Buffalo, University of Buffalo School of Medicine, 1878, aged 86, died, August 8, of uremia and nephrosclerosis

Alphonse L Shackelford, Dallas, Texas (licensed in Texas under the Act of 1907), aged 74, died, September 12, of coronary occlusion

Thomas J Appleton, Seattle, Chicago Homeopathic Medical College, 1890, aged 79, died, August 22, of arteriosclerosis and heart disease

Uryal C Ambrose, Cumberland, Ind, Louisville (Ky) Medical College, 1887, aged 79, died, September 3, of cerebral hemorrhage

Edward James Hogan, Overland, Mo, American Medical College, St. Louis, 1894, aged 77, died, September 1, of coronary occlusion

George Albert McEvoy, Newton, Mass, Harvard Medical School, Boston, 1899, aged 68, died, August 19, of coronary sclerosis

Charles Raymond Holshue, Shamokin, Pa, Jefferson Medical College of Philadelphia, 1891, aged 72, died, September 10

Ernest A Green, Grayville, Ill, Barnes Medical College, St. Louis, 1898, aged 70, died, August 29, of myocarditis

Thomas Jefferson Case, Delmont, S D Rusli Medical College, Chicago, 1889, aged 79, died, September 4

DIED WHILE IN MILITARY SERVICE

Herman Finkelstein, Roseland, N J, Long Island College of Medicine, Brooklyn, 1934, member of the Medical Society of New Jersey, formerly school physician, was called to active duty as a first lieutenant in the medical reserve corps of the U S Army March 6, 1941 appointed a captain June 29 of this year was stationed at Huntsville, Ala where he died, September 9 of acute brain abscess complicating acute catarrhal nasopharyngitis, aged 33

Millard Null Lawrence Philadelphia Temple University School of Medicine Philadelphia 1937, resident in surgery at the Temple University Hospital, was called to active duty as a lieutenant (junior grade) M C-V (G) U S Naval Reserve on August 16 of this year, aged 30 died, September 6, near Creeds Field Creeds, Va, of injuries received in an airplane accident

William Lee Tucker @ Cullman Ala, Tulane University of Louisiana School of Medicine New Orleans, 1928 first lieutenant in the medical corps of the U S Army stationed at Camp Polk La, on the staff of the Cullman Hospital aged 40 was run over by a train and killed, July 17, at DeQuincy La

Bureau of Investigation

DANGEROUS TO HEALTH

When Used as Directed

[EDITORIAL NOTE—These abstracts differ from other abstracts of Notices of Judgment issued by the Food and Drug Administration of the Federal Security Agency which have appeared in these pages in that they include reference to the fact that these nostrums were specifically declared to be dangerous to health when used in accordance with the directions given on the label by the manufacturer. The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the date of shipment, (4) the composition, (5) the type of nostrum, (6) the reason for the charge of misbranding and (7) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Aspirin Tablets—J R Watkins Company Winona Minn Shipped between July 3 1939 and April 19 1940 Composition acetylsalicylic acid acetophenetidin and caffeine citrate Declared misbranded because dangerous to health when used in the dosage or with the frequency or duration prescribed recommended or suggested in the labeling further misbranded because name falsely indicated chiefly aspirin present and amount of acetophenetidin not declared on the label—[D D N J F D C 328 March 1942]

Bromo Thein—Lockwood Laboratories Hammond Ill Shipped Aug 28 1940 Composition acetanilid with sodium and potassium bromides Misbranded because statement on label Each heaping teaspoonful contains 2½ grains acetanilid 2½ grains sodium bromide 2½ grains potassium bromide was false further misbranded because label failed to bear adequate warnings against taking the product in those pathological conditions wherein its use might be dangerous to health or cautioning against unsafe dosage methods or duration of administration in which its frequent or continued use might cause serious blood disturbances mental derangement and other serious effects—[D D N J F D C 281 November 1941]

Bull's 1001 Obesity Capsules—J W Bull Chicago Shipped March 24 1939 Composition thyroid and small amounts of sulfur licorice and nuxvomica Misbranded because dangerous to health if taken as labels directed—[D D N J F D C 153 April 1941]

Ealy's (Dr T F) Baby Powders—L O Ealy, Steubenville Ohio Shipped April 9 1940 Composition calomel plant material calcium carbonate and a small amount of saccharin Dangerous to health when used as recommended on label as a mild laxative for children—[D D N J F D C 277 November 1941]

Eczematone—Barlow Chemical Association Oklahoma City, Okla Shipped April 11 1940 Composition essentially alcohol (85 per cent) mercuric chloride (0.37 per cent) and water Misbranded because label falsely represented it as astringent nature in promoting healing and efficaciously treating minor irritating skin and scalp disorders sprains minor aches and pains and burning itching loose scaly dandruff Further misbranded because dangerous to health when used as recommended on label—[D D N J F D C 278 November 1941]

Flu Go—Flu Go Chemical Company Bessemer Ala Shipped Jan 22 1940 Composition essentially mineral oil ephedrine and aromatics including camphor and rose oil Misbranded because label falsely represented that the product constituted an efficacious treatment for influenza further misbranded because label did not accurately state the quantity of the contents also misbranded because label failed to contain warning that the product might be dangerous to health if taken as recommended—[D D N J F D C 382 November 1941]

Hexadrin—Murray Products Company San Francisco Shipped Nov 6 1939 Nasal device for injecting oily medication into the nostrils Misbranded because dangerous to health if used as directed in the labeling—[D D N J F D C 148 April 1941]

Ka No Mor—A G Luebert Coatesville Pa Shipped April 23 1940 Composition acetanilid caffeine and aspirin Misbranded because dangerous to health when used as suggested on labels and because falsely represented to be a safe and appropriate treatment for various pains aches and head colds—[D D N J F D C 143 April 1941]

Migro Headache Powder—C J Czarnecki Detroit Shipped Feb 6 1940 Composition essentially acetanilid sodium bicarbonate tartaric acid and milk sugar Adulterated and misbranded because acetanilid content per powder was greater than the 5 grains declared on the label Further misbranded because falsely represented as a safe and appropriate treatment for simple headache whereas it was dangerous to take as recommended—[D D N J F D C 146 April 1941]

Nervease Headache Powders—Nervease Company Boston Shipped March 27 1939 Composition in each powder 4.6 grains of acetanilid and 0.87 grain of caffeine with milk sugar and pink coloring Misbranded

because among other things falsely represented as efficacious for headache whereas it was dangerous to health if taken as the label suggested—[D D N J F D C 147 April 1941]

Neuroline—Link Chemical Company Emporia Kan Shipped Jan 30 1940 Misbranded because it contained more than the 60 grains of sodium bromide declared on the label and less than the 25 per cent of alcohol declared and because dangerous to health when used as recommended on the label—[D D N J F D C 145 April 1941]

One Minute Toothache Stick—One Minute Remedies Company St Louis Shipped April 12 1940 Composition essentially carbolic acid (23 per cent) paraffin cotton and small amounts of clove and cinnamon oils Misbranded because dangerous to health when used as directed on label and not efficacious for certain conditions specified—[D D N J F D C 330 March 1942] Another Notice of Judgment A J C P 108 was issued against this product in May 1942 under the Caustic Poison Act In this case it was charged that the preparation contained a dangerous caustic or corrosive substance (carbolic acid) in a concentration of 5 per cent or more and that the packages were misbranded in that the label did not bear the word Poison or any directions for treatment in case of accidental personal injury from the use of the preparation

Pachanga Mineral Water—Tripo M Lukovich trading as T M Lukovich D C Fluore Calif Shipped between Sept 5 and Nov 2 1940 Composition essentially the chloride sulfate carbonate and bicarbonate of sodium with a fluorine compound and a trace of an iron compound dissolved in water Total amount of dissolved matter was 2 per cent For the relief of certain stomach bowel liver and kidney disorders Declared misbranded because dangerous to health when used as directed in the labeling Further labeling failed to reveal the presence of fluorine and to give adequate warning against use by children—[D D N J F D C 326 and 327 March 1942]

Radioactive Cones—Thomas Radioactive Cone Company Inglewood Calif Shipped March 20 1940 Misbranded because of misleading labeling which failed to reveal that when used to impart radioactivity to water the drinking of such water might result in injury to the user further misbranded because label failed to bear name and place of business of manufacturer printer or distributor or to give the common name of ingredient or ingredients adequate directions for use or sufficient warnings against use by children and regarding unsafe dosage as the product was found to be dangerous to health when used with the frequency or duration prescribed recommended or suggested on the label—[D D N J F D C 331 March 1942]

Reed's Effervescent Bromo Sizz—Reed Products Company St Louis Shipped May 17 1940 Composition product contained acetanilid and would be dangerous to health when used as directed but was not labeled to show consequences that might result from its use Further misbranded because among other things statement on label regarding another ingredient sodium bromide approx 3% was not correct and did not inform user as to exact amount of sodium bromide consumed when preparation was taken according to directions—[D D N J F D C 332 March 1942]

Renton's Hydrocort Tablets—Pasadena Products Inc Pasadena Calif Shipped between Aug 31 1938 and Jan 3 1939 Composition cinchophen reported Misbranded because dangerous to health when used for pain or fever as suggested in the labeling—[D D N J F D C 144 April 1941]

Rock A Way Tablets—Gates Medicine Company, Charleston W Va Shipped Nov 28 1940 Composition in each tablet approximately 6 grains of boric acid with sodium bicarbonate and citric acid Purpose not stated Dangerous to health if used as label recommended—[D D N J F D C 280 November 1941]

Ultra Jel—Pynowl Laboratories Inc Chicago Shipped Aug 13 1940 Composition essentially water soap pine oil and combined iodine with no free iodine Misbranded because label falsely represented the product as efficacious for specific and nonspecific infections of the cervix and cervical canal because carton did not bear the common or usual names of the active ingredients and product was dangerous to health when used as recommended namely 1 to 5 cc injected into cervical canal and about 3 to 5 cc applied on wool tampon to be left in position from 12 to 20 hours—[D D N J F D C 333 March 1942]

Watkins Laxative Cold Tablets—J R Watkins Company Newark N J Shipped Feb 15 1940 Composition in each tablet 19 grains of acetanilid quinine alkaloids of belladonna and extracts of plant drugs including a laxative Misbranded because dangerous to health when used as directed on the label and because represented as a safe and appropriate remedy for such conditions as colds headaches sneezing and nasal discharge—[D D N J F D C 329 March 1942]

Young's (Dr) Rectal Dilators—F E Young and Company Chicago Shipped between May 10 and June 10 1940 Consisted of 4 hard plastic cylinders flanged at one end slightly enlarged and pointed at the other and varying in diameter from ½ inch to 1 inch and varying in length from 3 to 4 inches Misbranded because represented on label to be a simple harmless convenient, nonhabit forming ideal treatment to overcome constipation and hemorrhoids permanently by inducing natural and restore the sphincter muscles to normal conditions relieve blood congestion establish a healthy vigorous circulation and do many other things Further misbranded because dangerous to health when used with the frequency and duration suggested on the label—[D D N J F D C 335 March 1942]

Young's Preparation—O L Brunson Waycross Ga Shipped May 31 1940 Composition contained acetic acid and would be dangerous to health when used as label recommended for relief of itching skin and scalp—[D D N J F D C 154 April 1941]

Correspondence

PULMONARY EMBOLISM FOLLOWING VARICOSE VEIN INJECTION

To the Editor—Recent articles on pulmonary embolism following injection of varicose veins (*THE JOURNAL*, Aug 2, 1941, p 347, and April 11, 1942, p 1293) emphasize the danger of this complication. In most cases the treatment of varicosities is elected by the patient as a preventive and is not an emergency measure. Frequent occurrence of fatal complications would justly discourage the practitioner from undertaking this method of therapy and deter the patient from submitting to it.

In the correspondence in *THE JOURNAL* contradictory techniques are suggested. Dr Biggelsen (Sept 15, 1941, p 954) advises the use of mild initial injections. Drs Traub and Isaac (June 20, 1942, p 670) urge the use of large amounts of strong solutions to produce extensive damage to the intima, insisting that 15 cc of sodium morrhuate 5 per cent is a small dose of a weak solution. However, in the case of Num and Harrison two injections of 2 cc of this solution were sufficient to produce an indurated area measuring 8 by 3 cm surrounding an 11 cm segment of thrombosed great saphenous vein, persisting for six weeks.

I believe that the incidence of pulmonary embolism can be further reduced by preventing the filling of the "whole lumen" of the vein by a thrombus and by employing technique which will firmly anchor minimum thrombus formation and accelerate its organization and absorption.

In an article on the prevention of discomfort and disability in the treatment of varicose veins (*Am J Surg* 54 362 [Nov] 1941) the many advantages of the empty vein technique combined with adequate support are presented. Several of the technical procedures helpful in injecting collapsed varicosities are described.

Advantages of this technique in the prevention of complications are

- 1 "Whole lumen" thrombosis with accompanying disfiguring, painful, hard knots and strings, and severe inflammatory edema in the perivenous tissues are avoided. The resulting reactions are mild, causing little or no pain and discomfort, thus even the more sensitive patient will remain ambulatory during treatment. Bed rest is thought by many a factor in the production of emboli.

- 2 Blocking of varices is obtained by fusion of the opposing surfaces of the vessel and not by gross thrombosis. Organization and absorption of such obliterated vessels are accelerated with less chance for recanalization and loosening of blood clots.

- 3 Small amounts of sclerosing solution may be used, average dose 0.5 to 1.5 cc of not too strong a solution (Synasol), since dilution of the irritant by blood is reduced to a minimum. Small dosage is probably a factor in avoiding allergic reactions. In many of the 44 fatal cases reviewed by Vaughn and Lees large dosage, 40 to 90 cc of solution, was employed.

The absence of serious allergic reactions and emboli in my patients may be due to fortunate coincidence, as I am not inclined to believe that the techniques referred to assure absolute safety. However, there is some reason to assume that minimum thrombus formation, its firm anchorage, its more speedy organization and absorption further reduce the incidence of pulmonary embolism.

Unfortunately the advantages of adequate support in the treatment of varicosities are often overlooked. Heyerdale and

Weissman (*Proc Staff Meet, Mayo Clin* 52 823 [Dec 29] 1941) state that "only moderate pressure is necessary to collapse a superficial vein," advising the patient to remove the gauze pad at the end of two hours, "by which time it will have served its purpose," which is "temporary compression to facilitate thrombosis and to avoid escape of the contents of the vein." This technique is described as satisfactory and dependable for all types and sizes of varicosities. I insist on the continued use of effective support until after disappearance of induration and tenderness over the occluded vessels.

The following procedures may be considered additional precautionary measures for the prevention of pulmonary embolus.

- 1 Do not inject varicosities in the presence of edema. Eliminate the edema first by the use of effective support.

- 2 Do not inject varicosities in the presence of ulcerations, whether infected or clean. The use of sulfonamides locally, combined with adequate support of the superficial venous circulation, will usually control the infection and the patient may remain ambulatory. It is not necessarily advantageous to inject the varicosities, even though they are the etiologic factor. The inflammatory reaction produced, even if mild, does not accelerate healing. Moreover, effective support judiciously applied stimulates epithelization and results in a smoother and more cosmetic scar.

I. A. BRUNSTEIN, M.D., New York

"CONSTITUTIONAL INADEQUACY"

To the Editor—In an article on constitutional inadequacy that appeared in a recent issue of *THE JOURNAL*, Alvarez has crystallized certain ideas that have appeared in the medical literature from time to time. Essentially the idea put forth is that in this syndrome we are dealing with a whole body that is sick rather than with a single organ and that even if we find a diseased organ and remove it the person does not get well.

This idea represents a departure from the older doctrine of Virchow and is bound to have a great effect on medical thinking in the future. In the latter part of the last century at a conference in Rome Virchow said "We do not recognize a body that is diseased in all its parts, but for each disease we must find a seat in some organ of the body."

In 1942 Alvarez said "We must stop looking hopefully for some one lesion to explain the disability. They cannot be cured, as they hope to be, by the discovery and eradication of any one local disease."

This departure represents a turning point for a clearer understanding and handling of many of the complex cases that we see in our clinics today.

S. K. ROBINSON, M.D., Chicago

FLATULENCE

To the Editor—May I supplement by one item the excellent paper of Dr Alvarez on "What Causes Flatulence?" which appears in the September 5 issue.

The French have a saying "Les vents precede la pluie" (Winds precede the rain). French clinicians have taken that over into the clinical pathology of hepatic cirrhosis by saying that flatulence precedes ascites in many a case of cirrhosis of the liver with portal obstruction and consequent congestion of the intestinal wall. Many physicians will corroborate this observation. We should add hepatic cirrhosis to the list of flatugenerators.

GEORGE MANNHEIMER, M.D., New York

Council on Medical Education and Hospitals

CONTINUATION COURSES FOR PRACTICING PHYSICIANS

In accordance with the plan of the Council on Medical Education and Hospitals, advance information concerning continuation courses for practicing physicians available in the various centers is published quarterly. The following list consists of courses

beginning during the period Oct 15, 1942-Jan 15, 1943. It is hoped that this material will be useful to physicians seeking opportunities for postgraduate work. Physicians called on to assume new responsibilities because of the war and physicians who are returning to practice may find here listed courses which will be of help to them. Since many of the classes are necessarily limited, those who contemplate enrolling in any of these courses are urged to communicate as early as possible with the proper executive officer.

H G WISKOTTEN MD
Secretary, Council on Medical
Education and Hospitals

Continuation Courses for Practicing Physicians October 15, 1942-January 15, 1943

Institution	Schedule of Course	Title of Course	Number of Students Accepted	Registration Fee and/or Tuition
ALLERGY —See also Dermatology & Syphilology Medicine				
Tufts Medical School 30 Bennett Street Boston Mass. Write to Dr Samuel Proger Chairman Postgraduate Division	Oct 10 '23 Full time	Diagnosis and Treatment of Allergic Conditions	Minimum 6	\$25

- 1 A registration fee of \$5 covers all courses taken within the year
- 2 Register two to six weeks in advance
- 3 Grants may be made from a scholarship fund
- 4 Specialists who have had adequate preliminary training and/or experience
- 5 If two or more students register for the course at the same time a reduction in the fee will be made
- 6 Special parts may be taken
- 7 No registration fee for physicians in military service
- 8 Includes a subscription to Modern Concepts of Cardiovascular Disease
- 9 Physicians who have had adequate preliminary training and/or experience
- 10 A monthly stipend is paid
- 11 Applicants approved by instructor department head etc
- 12 A temporary license to practice medicine in the state is required
- 13 If taken in conjunction with the next course above/below (Gastroscopy/Peritoneoscopy) the fee for the combined course will be \$125
- 14 Members of the association
- 15 Half fee to physicians in the military service
- 16 Medical Reserve Officers United States Army

- 17 Officers of the United States Army, Navy or the United States Naval Reserve on active duty
- 18 Officers in key positions in the Medical Department on active duty
- 19 Returned on satisfactory completion of the course
- 20 Male physicians only
- 21 For physicians licensed to practice in the state
- 22 Maintenance provided
- 23 The same course is given for Negro physicians at Lincoln Hospital Durham N C
- 24 Physicians who wish to specialize
- 25 Plus a matriculation and/or incidental fee
- 26 Longer courses may be arranged in units of twelve sessions each
- 27 Microscope required
- 28 Plus a laboratory fee
- 29 Assistantships Internships residencies available
- 30 A faculty course for staff members of mental institutions
- 31 Public health officers and other qualified persons who are not applying for a degree
- 32 Operative work on the cadaver may be taken on payment of an additional fee
- 33 Fellows and Junior Candidates of the college
- 34 Expenses and a per diem are paid

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts Neurosis Resulting from Traumatic Shock Compensable—A large amount of rock and muck accidentally fell on the shoulders, neck and back of the workman while he was engaged in the performance of his duties as a miner. His shoulders and neck were bruised and a gash was inflicted on the back of his right hand which required several stitches to close. He remained away from work for four days, resumed his work for about two weeks, laid off for a week and then worked two days, by which time he found the pain to the back of his neck and shoulders so great that he could not continue. About ten days later his left arm suddenly became paralyzed and his condition continued to grow worse, until at the time of the hearing on his claim for compensation under the workmen's compensation act of Arizona his left shoulder and arm were practically paralyzed. The industrial commission of Arizona awarded him compensation, finding that he had sustained an injury by accident arising out of and in the course of his employment. The employer then appealed to the Supreme Court of Arizona.

The employer contended that the workman's present condition was not one which would entitle him to compensation under the workmen's compensation act of Arizona, arguing that the workman's condition, while real and in no sense the result of malingering, was one of functional paralysis caused by an anxiety neurosis induced by the accident alone and not by the injury, and that under the Arizona law the condition was not compensable. The workman contended that his paralytic condition was a neurosis resulting directly from an injury received in the industrial accident. Physicians who examined the workman, said the court, unanimously concluded that the paralytic condition was functional and not organic and was "suggested" by the industrial accident. The employer contended that the conclusion of the examining physicians is a specific statement that the injury had no connection with the admitted neurosis but that the latter was an anxiety neurosis resulting solely from the accident itself. On the other hand, the workman contended that the physicians were not familiar with the technical legal interpretation of the word "accident" as used in the workmen's compensation act and used the word merely in a colloquial sense of meaning both the accident and the injury resulting therefrom on July 12. We think, said the court, that the industrial commission was justified in finding, as it must have, that it was more probable that in using the word "accident" the physicians referred to the entire picture of the situation as it appeared on July 12 rather than to the technical accident alone, excluding the admitted traumatic injury resulting therefrom.

All the parties, continued the court, agree that the workman's condition is a post-traumatic neurosis of some kind. A neurosis is a disease. Many medical authorities divide post-traumatic neurosis into three general classes, post-traumatic neurasthenia, post-traumatic anxiety neurosis and post-traumatic hysteria neurosis. The symptoms in the neuroses are generally subjective in their nature, and, while some of the symptoms of each of these three classes are similar, yet there are others which are distinctive enough to justify the classification. On consideration of the testimony of all the examining physicians, together with that of the workman, we think that the industrial commission was fully justified in believing that the workman's condition was what is known as post-traumatic hysteria rather than anxiety neurosis and that this former class of neurosis very commonly if not usually, arises from shock resulting from some accident. In view of the history of the case, we think that the natural, if not the irresistible, conclusion is that the workman's condition was a post-traumatic hysteria neurosis resulting from a shock caused by the accident of July 12. Now under the workman's compen-

sation act of Arizona the only condition that is compensable is a personal injury arising out of and in the course of employment, and it is specifically stated that a disease is not compensable unless it is a disease resulting from the injury. Is the workman suffering from a disease resulting from the injury? The answer depends on whether shock, in the medical sense of the term, is itself legally an injury. The English courts have always held that a nervous shock resulting from an accident is just as much an injury as any muscular or bodily consequences which are objectively discernible. This ruling is followed in many American cases in which a similar question has arisen, and this sort of holding is justified in reason in our opinion. We therefore hold that a nervous shock caused by an accident arising out of and in the course of an employment is a compensable "injury" within the meaning of the Arizona act. Since a shock is a compensable injury and neurosis is a disease, a hysteria neurosis caused by a shock is a "disease" resulting from the injury. On the record in the present case, the industrial commission was justified in finding that the workman's condition was due to a disease resulting from an injury caused by an accident arising out of and in the due course of his employment.

The court further held that there was sufficient evidence from which the industrial commission might have found, as it must have in order to make its award, that the workman's neurosis was the result of the traumatic shock which he received and was not due to a deep set fear or apprehension of imaginary ailments that might follow as a result of his injury. If the workman's condition had been due to the latter possibility, the condition would not have been compensable in view of previous decisions of the Supreme Court of Arizona in *Pierce v. Phelps Dodge Corp.*, 42 Ariz. 436, 26 P. (2d) 1017 and *Phelps Dodge Corp. v. Industrial Commission of Arizona and Lads*, 46 Ariz. 162, 49 P. (2d) 391.

For the reasons stated the award of compensation in favor of the workman was affirmed.—*American Smelting & Refining Co. v. Industrial Commission*, 123 P. (2d) 163 (Ariz., 1942).

Use of Fifteen Year Old Boy as Skin Donor Without Consent of Parents as Constituting Assault and Battery—The cousin of the plaintiff, a 15 year old Negro boy, was so severely burned that she became a hopeless cripple. She was attended in the charity clinic of a hospital by the physician defendant, a specialist in plastic surgery. The physician advised a skin graft provided the blood of the donor matched the patient's blood. After a number of unsuccessful efforts to match her blood were made, it was ascertained that the plaintiff's blood matched and, unbeknown to his mother with whom he lived and who was ill at the time and knew nothing of the arrangements, the boy permitted the physician to perform an "operation," in the words of the court, on his side. After the "operation" the boy returned home and while there advised his mother that he was returning to the hospital to have his side "fixed up." He remained in the hospital about two months, during which time a number of operations were performed on him. A tube of flesh was cut and formed from his armpit to his waist line and at the proper time one end of the tube was attached to his cousin. The result was unsatisfactory because of improper circulation of the blood through the tube. Accordingly, the tube was severed after the boy had lost a considerable amount of blood and himself required transfusions. The tube of flesh was later removed and the plaintiff was released from the hospital. Subsequently, the plaintiff, by his next friend, his mother, sued the physician defendant to recover damages for assault and battery on the theory that the physician had not obtained proper authority before operating on the minor plaintiff. At the conclusion of all the evidence the court instructed the jury that if they believed that the plaintiff himself was capable of appreciating and did appreciate the nature and consequences of the operation and actually consented, or by his conduct impliedly consented, their verdict must be for the defendant. There was a verdict for the physician, and from a judgment entered thereon the plaintiff appealed to the United States Court of Appeals for the District of Columbia.

The plaintiff contended that the trial court erred in the instruction because a performance of an operation on a minor without the consent of his surviving parents constitutes an assault and battery. The general rule is, said the appellate court, that the consent of the parent is necessary for an operation on a child. A surgical operation is a technical battery, regardless of its results, and is excusable only when there is express or implied consent by the patient or, stated somewhat differently, the operating physician is liable in damages if the operation is unauthorized. Here the question is whether the consent of a boy 15 years of age dispenses with the necessity of consent by his parents. The trial court decided that it did and in so deciding it followed section 59 of the American Law Institute's Restatement of the Law of Torts, which states that if a child is capable of appreciating the nature, extent and consequences of the invasion, his assent prevents the invasion from creating liability, even though the assent of the parent is expressly refused. The rule adopted by the American Law Institute, continued the court, is bottomed on the principle that the very nature of rights of personality is freedom to dispose of one's own person as one pleases. But even if this conclusion is granted, it overlooks the infancy exception to such a rule. In deference to common experience, there is general recognition of the fact that many persons by reason of their youth are incapable of intelligent decision, as the result of which public policy demands the legal protection of their person as well as their property rights. The universal law, therefore, is that a minor cannot be held liable on his personal contracts or contracts for the disposition of his property. So also in the case of female infants the age of consent has been raised in many states from 12 years to 18 years. Likewise in most states the legal age for marriage, both of males and females, has been greatly increased over the common law standard, and where either party is under 21 years of age the consent of parents is required. Hence it is not at all surprising that, generally speaking, the rule has been considered to be that a surgeon has no legal right to operate on a child without the consent of his parents or guardian. There are, of course, exceptions to this rule. One of them is in cases of emergency, when obviously an operation is necessary. Others, perhaps in cases in which the child has been emancipated or where the parents are so remote as to make impracticable the obtaining of their consent in time to accomplish proper results. And where the child is close to maturity it has been held that the surgeon may be justified in accepting his consent. *Bakker v Welsh*, 144 Mich 632, 108 N W 94. But in all such cases the basic consideration is whether the proposed operation is for the benefit of the child and is done with a purpose of saving his life or limb. The circumstances in the present case are wholly without the compass of any of these exceptions. Here the operation was entirely for the benefit of another and involved sacrifice on the part of the infant of fully two months of schooling, in addition to serious physical pain and possible results affecting his future life. This immature Negro boy was subjected several times to treatment involving anesthesia, blood letting and the removal of skin from his body, with at least some permanent marks of disfigurement.

As authority for his contention that the consent of the infant under the circumstances was a sufficient authority for the performance of the operative procedures, the physician cited, in addition to the statement in the Restatement of the Law of Torts above referred to, *Bakker v Welsh*, 144 Mich 632, 108 N W 94 where an operation was performed on a 17 year old boy without the express consent of his father, the consent of the minor ultimately being held to be sufficient authority to authorize the surgeon to operate. But said the appellate court, the question here is different from that in any of the cases to which our attention has been drawn, for here we have a case of a surgical operation not for the benefit of the person operated on but for another, and also so involved in its technique as to require a mature mind to understand precisely what the donor was offering to give. We believe, therefore, that the trial court should in the circumstances have instructed that the consent of the parent was necessary.

Undoubtedly the case from the standpoint of the physician defendant is a hard one. At all times he was rendering, without compensation, his skill and professional services to alleviate pain and suffering. Doubtless this fact weighed with the jury, who regarded his activities in the matter as impelled wholly by humane and charitable motives. But by his own testimony it clearly appears that he failed to explain even to the infant, the nature or extent of the proposed first operation. As to those which followed, he claims that the matter was fully explained. And there is evidence that during the ensuing progress of the experiment the mother, too, was apprised of her son's heroism and gloried in the newspaper notoriety which followed and which apparently resulted in public contributions of money for the boy's future education. Whether this attitude of the mother was a sufficient ratification, we need not here decide, since that question is not now at issue. However, if on a new trial the evidence in this respect is substantially the same, the question whether or not there was consent by ratification by the mother should be submitted to the jury under appropriate instructions. And if, after the mother learned of the preliminary operation, she made no objection thereto but publicly expressed her pride in her son's courage and without remonstrance allowed him to return for the completion of the experiment, such action on her part would be tantamount to consent by implication and that, under the circumstances, would be sufficient authority on which the physician could proceed with his operative procedures.

For the reasons stated, the judgment in favor of the physician was reversed and the cause was remanded for a new trial.—*Bonner v Moran* 126 F (2d) 121 (1941)

Malpractice Services of X-Ray Technician as Constituting Practice of Medicine—In this case, the supreme court, special term, New York County, held that the services rendered by an x-ray technician in a hospital constituted the practice of medicine as defined by subdivision 7 of section 1250 of the Education Law. Therefore an action to recover damages for injuries caused by the negligent administration of roentgen treatment by such technician was governed by the two year statute of limitations applicable to malpractice actions rather than by the three year statute of limitations applicable to actions for negligence generally.—*Leitch v Mulcahy*, 31 N Y S (2d) 874 (N Y, 1941)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Electrometric Timing of Human Ovulation—In determining with certainty the time of ovulation in 7 women (one hundred and fifty daily records of the menstrual cycle) Langman and Burr developed an electrical simplified technic which makes it possible to record the changes in voltage gradient which exist between the cervix uteri and some different point on the surface of the body, such as the ankle. The studies showed that most commonly throughout the menstrual cycle the cervix was positive to the ankle from 5 to 25 millivolts. In nine of the fourteen cycles studied the cervix became negative, an equivalent amount on at least one day of each cycle. In four of these the cervix remained negative for two days. The negativity appeared on the third, sixth, seventh, eighth, thirteenth, fourteenth, eighteenth or twenty-first days. In five cycles either no negative shift occurred or it was equivocal. The general muscular activity of the uterus was reflected in changing potentials and that this activity is an important element in the physiology of the generative tract was shown by the fact that all the electrical records showed a higher level of activity as early as the sixth and as late as the twenty-first day of the cycle. An additional interesting observation was that on the fourth or fifth day prior to the onset of a succeeding menstrual period, the positivity of the cervix increased to as much as 30 or 35 millivolts and usually

remained there until the actual onset of bleeding. With the onset of the flow the voltage difference dropped to more nearly the normal 15 millivolts. There are a good many variables involved in the physiology of the generative tract. This is true also of ovulation, but the fact that it was possible to get at least one positive correlation makes it worth while to extend these studies. While the procedure is relatively simple, certain safeguards against artefacts must be employed as the hot lead goes to the cervix and not to the wall of the vagina. Unsuspected grounds on the patient and air bubbles in the leads to the electrodes are sources of error. Interference from other electrical devices can usually be recognized without difficulty. The injection of estrogen produced a pronounced effect on the electrical record. The data suggest the possibility of studying the effect of a variety of hormones on generative physiology.

Prostigmine Methylsulfate and Delayed Menstruation.—To determine the efficacy of prostigmine methylsulfate in differentiating between delayed menstruation and early pregnancy, Winkelstein investigated 90 women complaining of temporary amenorrhea who asked for such a diagnosis. All injections were given intramuscularly once daily for three days. If menstruation was precipitated before the series was completed, further injections were not given. Excluding temporary vertigo and nausea no untoward effects ensued, except for 1 patient, who collapsed. Shock lasted for about fifteen minutes. Recovery was spontaneous and complete. There was no explanation for this reaction. The prostigmine successfully differentiated early pregnancy from temporary amenorrhea by inducing delayed menstrual flow in about 87 per cent of the women. The responses to prostigmine were checked against a physical examination and, when necessary, against the Aschheim Zondek test. In the nonpregnant, bleeding started after an average interval of fourteen hours following the last injection. In contrast to the Aschheim Zondek test, which is known to err, especially on the negative side, in the early stages after the first skipped period all 6 patients tested during the first week of amenorrhea were accurately diagnosed as pregnant by prostigmine. However, discrepancies occurred in both positive and negative responses. Eight nonpregnant patients continued with their amenorrhea despite the injections, and 4 who were pregnant bled following the injections. This is the greatest hazard in using the drug. The prostigmine test should be useful in keeping many women from unnecessary manipulations at the hand of the abortionist.

Vitamins B₁ and B₆ in Vomiting of Pregnancy—Eighty-one women suffering from hyperemesis of pregnancy obtained almost complete relief from nausea and vomiting by the administration of vitamins B₁ and B₆ in varying doses at irregular intervals. Willis and his associates gave the vitamins intramuscularly or intravenously. Relief occurred more often and more completely with the use of vitamin B₆. Many patients returned for injections only when symptoms reappeared. There were no undesirable reactions. Two patients were also relieved of an accompanying migraine. The effect of this vitamin on vomiting due to other drugs, morphine and sulfanilamide, should be investigated.

Vitamin E and Premature Labor—The only therapy that Shute used for 46 women threatened with premature delivery was vitamin E. Premature expulsion of the fetus at any stage of pregnancy may be due to more than one single cause, but vitamin E equilibrium appears to be the most important primary cause. An excess of estrogen was discovered early in the pregnancy of 73 per cent (76 per cent went to term) of the 40 patients tested for it and also by the success of vitamin E in preserving many of these precarious gestations. Probably more of the pregnancies could have been preserved had larger doses of vitamin E been used prophylactically. Results have improved greatly since the author has begun using larger doses. The therapy should be maintained until delivery at term. Only potent preparations should be used, the best is a fresh refrigerated bulk wheat germ oil or a synthetic alpha

tocopherol Much more bleeding can occur in late than in early pregnancy without unduly jeopardizing its integrity This is probably due to the greater proportion of adequately adherent placentas that remain undisturbed in the former Many times the estrogen assay has foretold trouble months before it was clinically obvious The dose of vitamin E required to preserve a precarious pregnancy rises gradually toward term Only 3 of the 41 live children in the series were defective, cleft palate and harelip, congenital bile duct obliteration and meningocele with clubfeet and ectocardia Only 1 of the 3 defective children as long as three months Therefore the lives of 38 children were preserved by nature or vitamin E or both Doubtless some of the threats to premature delivery would have subsided without the administration of any treatment, but the author ascribes the outcome more to vitamin E than to fate

Chemotherapy in Osteomyelitis—Wilensky discusses his experience with the sulfonamide drugs in the treatment of acute inflammation of the bones of bacterial origin (acute osteomyelitis) and of chronic osteomyelitis when a recrudescence or an exacerbation made it an "acute" case Such chemotherapy has not produced the startling results that it has had in some other diseases, notably pneumonia The results have varied from negative to occasional extremely satisfactory effects They have been relatively good in the phase of general infection (bacteremia) and relatively without effect and sometimes dangerous as far as the local focus of osteomyelitis in the bone was concerned The results were not always predictable, owing to occasional difficulty in maintaining the proper concentration, necessity of matching the proper drug to the provocative organism, occurrence of certain toxic effects and the inherent difficulty in removing inaccessible foci of infection by surgical means Chemotherapy has not prevented spread of the pathologic condition or the occurrence of complications Sometimes the proper interpretation of good results is difficult, as unaided spontaneous beneficial changes undoubtedly occur In making any conclusions regarding the action of any of the new chemotherapeutic drugs in osteomyelitis, the possibilities for spontaneous unaided recovery should be remembered

Hemorrhage in the Nontuberculous—Hemoptysis frequently has its origin in lesions other than tuberculous To investigate the nontuberculous bases for tracheal and bronchiopulmonary hemorrhage Jackson and Diamond made a survey of 436 such patients observed at Temple University Hospital from January 1930 to July 1941 Patients with evident parenchymal disease, those whose hemoptysis was due directly to trauma inflicted by aspirated foreign bodies and those with lesions outside the tracheobronchial tree and the lungs were eliminated The principal lesion was bronchiectasis in 138, primary bronchial carcinoma in 82, tracheobronchitis in 74, pulmonary abscess in 51, no evident disease in 34, nonsuppurative pneumonitis in 15 suppurative pneumonitis in 11, bronchial adenoma in 11, secondary pulmonary cancer in 6, lobar atelectasis in 4, primary tracheal carcinoma in 2, and in 8 there were eight different principal lesions, such as streptothricosis, broncholithiasis and tracheal osteoma Fatal hemoptysis was experienced by only 3 of the patients, each of whom had a pulmonary abscess A hemorrhagic focus could be seen on bronchoscopic examination in 25 per cent There was no endoscopic evidence of recent or active bleeding from a vascular lesion in the tracheobronchial tree of any of the patients Ulcerative lesions probably existed in the smaller bronchi of the patients (about one fourth) for whom the precise cause of the hemoptysis could not be determined Despite the fact that in 90 per cent of the patients with hemorrhagic bronchial cancer the neoplasm was situated in a bronchoscopically accessible bronchus and that bronchoscopy was performed soon after the first hemorrhage, the process in all but 1 was too far advanced to permit surgical cure If a successful therapeutic result is to be achieved for these patients bronchoscopy must be done and the diagnosis made before the hemoptysic stage

Cadmium in Treatment of Tuberculosis—Negative results were obtained by Dormer and his associates in the treatment of 26 tuberculous patients with cadmium sulfide The optimistic reports of previous workers were not confirmed

Undiagnosed Tuberculosis—As part of its case finding program one of the New York City Department of Health tuberculosis clinics has utilized its facilities and personnel to study roentgenologically an adult group of apparently healthy low income persons Cut paper films, 14 by 17 inches, were used in standard x-ray equipment for the 3414 persons from 15 to more than 75 years of age examined Miller and Henderson state that 1063 per cent of all males and 636 per cent of all females examined had chronic pulmonary tuberculosis, while for significant tuberculosis the figures were 455 and 167 Twenty nine of the 100 clinically significant cases were proved to be active All forms of tuberculosis were more common in the older than in the younger individuals Significant tuberculosis and active tuberculosis were approximately three times as common in persons more than 40 as in younger ones Twelve of the 13 with positive sputum were more than 50 Case finding should be more vigorous in higher age groups

Sodium Sulfathiazole Iontophoresis—According to Boyd iontophoresis of a 5 per cent solution of sodium sulfathiazole with 1 milliampere for two minutes when compared with a corneal bath of equal duration increases the corneal and aqueous humor concentration of sulfathiazole by three times. With a current of 2 milliamperes the concentration in the cornea and in the aqueous humor is increased ten and nine times respectively. There was no ocular damage with the use of a current that produces a concentration of sulfathiazole consistent with an optimal bacteriostatic effect.

Meningococcal Infection Treated with Sulfonamide Drugs—The all embracing term meningococcal infection is suggested by Klein instead of meningococcal meningitis, as the disease, in addition to the pronounced toxemia, consists of three stages: the initial or nasopharyngeal, the bacteremic and the meningial. It may become arrested in either of the first two stages, which may account for an increase in carriers preceding and during an outbreak, and meningococcal bacteremia may exist without meningitis for weeks or months or even years. Reports from European centers have shown a definite increase in the incidence of this affliction associated with the present hostilities. The figure for Canada in 1940 was more than double that of 1938 and 1939. The United States of America showed no increase in the notification of this disease. The advent of the sulfonamide compounds has raised the question as to whether serum is required in conjunction with them. Every form of therapy, sulfonamide or serum, acts as an adjunct to the immunity mechanism of the

patient under treatment. Sufficient amounts of sulfonamides should be given to relieve the immunity mechanism of as much burden as possible. Low doses are not safe, as too great a burden is thrown on the patient's natural resources with which the body may not be able to cope. A large initial dose should be given, because this shortens the total period of treatment. Analysis of a collected series of 41 patients with meningococcal infection from 1937 to the early part of 1941 shows that 2 had meningococcal bacteremia without meningitis and that 39 had meningitis, 6 of them died, giving a gross mortality of 14.6 per cent. The deaths of 5 patients could be eliminated, as they were ill for weeks before treatment was begun, leaving one death in 36 patients, a corrected mortality of 2.7 per cent. Chemotherapy was used alone in the treatment of most of the patients: sulfapyridine more than sulfanilamide. Serum was apparently not essential as an adjunct. Serum should not be administered intrathecally but may be used intravenously or intramuscularly. Therapeutic lumbar punctures are unnecessary when patients are treated adequately and early in the course of the disease.

Vitamin Therapy of Muscular Dystrophy—Hawke administered moderate amounts of vitamins B₁, B₆, and E to 7 children with muscular dystrophy. In no instance did any definite objective improvement occur.

Potassium Thiocyanate in Hypertension—Canady and Allen attempted to determine whether the thiocyanates could be used safely and effectively in the treatment of 19 private unselected hypertensive patients. Their systolic pressure had remained above 200 mm and their diastolic pressure above 120 mm on theobromine, nitrate or sedative therapy for three months to three years. During treatment the patients were seen at regular intervals and were questioned for any toxic symptoms. The blood thiocyanate level was determined at regular intervals. Five of the patients had severe renal damage. The result was considered excellent when the systolic pressure fell to 170 mm or less with a corresponding fall in diastolic

pressure, good when there was some decrease in blood pressure and poor if no fall occurred. The results were excellent with 10 good with 2 and poor with 7 patients. The poor results with 5 of the 7 patients were for those with severe renal damage. Although 3 of this group had a significant fall in blood pressure, they were not symptomatically improved. These 5 patients have died, the cause of death being uremia in 3 instances and cerebral hemorrhage in 2. Their deaths could not be attributed to the thiocyanate, as it was discontinued many months before death. Satisfactory symptomatic and blood pressure improvement was maintained with a thiocyanate blood level of 5 to 12 mg per hundred cubic centimeters. The amount of potassium thiocyanate necessary to maintain a satisfactory level varied with each patient. The maximal daily dose was 1 Gm. The authors believe that the drug should be discontinued if no improvement occurs with a satisfactory blood thiocyanate level and should not be used for patients more than 60. No other form of therapy has proved successful for elderly patients. The drug should never be used unless frequent blood thiocyanate determinations are made.

Weil-Felix Reaction and Proteus and Pseudomonas Aeruginosa Infection.—The observation that some patients with infection caused by a member of the genus Proteus showed positive Weil-Felix reactions prompted Dammin and Billings to test the serums of 14 patients from whom either the Proteus mirabilis or the Proteus vulgaris strain was isolated. In 1, Pseudomonas aeruginosa also was recovered. The organism cultured from each is not assumed to have played a major role in causing or determining the course of the patient's illness. Only the serums of those patients in which appreciable agglutinative titers developed to their own organisms showed agglutinins in significant titer for the Weil-Felix antigens. It was particularly those patients in whom agglutinins developed to an O antigen prepared from the organism

isolated from them that significant titers for the Weil-Felix antigens developed. In an attempt to detect the probable presence of an antigenic component common to the Weil-Felix strains and those isolated from the patients, it was found that a minor antigen is common to human strains of Proteus and Pseudomonas aeruginosa and to the X strains of Proteus routinely employed in the Weil-Felix test. The existence of this antigen explains the positive Weil-Felix reactions exhibited by patients infected with Proteus and Pseudomonas aeruginosa. When tested with the Weil-Felix antigens, the serums of these patients show an agglutinative pattern different from that in the rickettsial diseases. The study indicates that the strains of Proteus isolated from patients are most closely related antigenically to Proteus OXX.

Radiation Cancer.—Radiation cancer develops in three groups of persons: those who work with roentgen rays and radioactive elements, those on whom roentgen rays or radium is used during a long time for diagnostic or therapeutic purposes and industrial workers who come in contact with radioactive elements. The exact amount or dose of radiation necessary to produce radiation cancer, Silverstone points out, is not known, nor is it as important as the fact that the radiation must be administered over a long continuous exposure or many intermittent exposures. Radiation in doses sufficient to destroy diseased tissue completely produces radionecrosis, and radionecrotic tissue seldom undergoes malignant change, but cancer may occur in the viable tissue at the edge of the radionecrotic area. If the dose produces incomplete destruction or differential destructive effects on various tissue components, a complex balance of necrosis and repair is set up which may eventually lead to malignant neoplastic formation. In such an injury, degenerative and regenerative processes are operative at the same time. Both processes are progressive and continue indefinitely even though the radioactive agent is withdrawn. This stage corresponds to the long latent unpredictable and variable period between their radiation and the appearance of a neoplasm. It may vary from one to twenty-five years, during which time both reparative and degenerative processes are active but neither repair nor necrosis is ever complete. Finally a stage is reached in which the reparative processes undergo increased activity and a transition to neoplastic activity, frequently multiple, occurs. These events are best observed in the skin, every stage of transition may be found from simple hyperplasia of the epithelium to infiltrating squamous cell carcinoma but in a stroma characterized by extensive hyalinization and poor vascularity. The type of neoplasm depends not on the nature of the injurious agent but on the type of tissue affected. The origin of the neoplasm is limited to the irradiated tissue, but once established, it behaves like any other malignant neoplasm of similar structure and anatomic site.

Henoch's Idiopathic Purpura—When cutaneous hemorrhage is combined with colic it is Henoch's purpura which is related to various erythemas, urticaria and angioneurotic edema. The condition, Hadley points out, may occur with or without purpura, and when purpura is absent many patients have undergone surgical operations for supposed appendicitis. The abdominal symptoms are colicky in type and are due to internal hemorrhages and to intestinal swelling and distention. There is edema in many cases around the face, hands and feet. The symptoms are anaphylactoid. The disease not only may simulate abdominal disease but may cause it. Vitamin C treatment does not produce any definite clinical results.

Typhus—Joseph states that there is no epidemic typhus in the United States today but that endemic typhus is present and is becoming more widespread and frequent. Endemic or murine typhus is primarily a disease of rats and is transmitted only incidentally from rat to man by the tropical rat flea, never as far as is known from one human being to another. It can and does occur in all classes and not as the epidemic, only in the lower economic strata. This is the form seen at Charity Hospital. Mild typhus was not described as occurring in Louisiana until 1929. Only 130 cases were reported in Louisiana during the following ten years. In 1939 117 cases were reported in 1940 118 cases and in 1941 194 cases. During 1941 there were almost 3,000 cases in the United States and of these 94 per cent were reported from the coastal southeastern United States and Texas. Of the 194 cases in Louisiana, 44 were observed at Charity Hospital. In nearly every case there was a definite history of having rats in the home or working

environment, or both. Of the 44 patients 24 had actually handled rats or mice or had a history of having had flea or other insect bites. Blood serum agglutination of suspensions of *Bacillus proteus* OX19 developed in all the patients. The disease appeared most often in urban environments and in late summer and early fall. Although there is no specific treatment, there were no deaths and the complications and sequelae were negligible. Sulfonamides and quinine were used without beneficial effect. A vaccine for immunization is to be had but as far as endemic typhus is concerned rat control is the only prevention.

 *Arterial Hypotension T M Durant Philadelphia—p 1188

Arterial Hypotension—Durant limits his discussion to the so called essential hypotension and postural hypotension. Arterial hypotension is not a disease entity. The relationship of low blood pressure to lassitude, dizziness, headache, lack of stamina, nervousness and cold extremities must be considered. Yet persons with hypotension do not all have these complaints. Therefore the problem must be analyzed still further to discover, if possible, why some persons with hypotension complain bitterly whereas others do not. The one striking feature of the hypotensive person with symptoms is that he is characteristically, of linear build is usually underweight and is often of sedentary habits, partakes of little exercise and frequently manifests nervous instability and has habitual hypothermia. The question is whether the symptomatology is due to the hypotension or to the constitutional makeup and physical condition. There is evidence that it is possible to alleviate completely the symptoms of most of these patients by correcting the weight deficiency by persistent graduated exercises and dietary measures. The symptoms disappear even though the blood pressure remains unaltered. Drugs which raise the blood pressure without psychic stimulation do not completely relieve the complaints even when the pressure becomes average. Therefore the hypotension is not the primary factor in the symptomatology but a symptom of subnormal body tonus. The hypotensive individual without complaints is generally in good physical trim whose circulatory adjustments (as in the athlete) have been developed to the highest plane of efficiency. Therefore "essential" hypotension is not of itself a disease, but in the undernourished asthenic individual complaining of fatigue and related symptoms it should direct attention to the treatment of the general condition. The relationship of blood pressure to posture is close. There are persons who often have a normal blood pressure when examined, but if the determination is made after they have stood several minutes the result will be entirely different. The ability of a subject to maintain the upright position without circulatory embarrassment is directly related to the level of muscle tonus. Other factors which may greatly influence the adaptive mechanisms and thus contribute to orthostatic hypotension are nervous and fatigue, the postinfectious convalescent state, pregnancy and disease of the central nervous system. The patient with postural hypotension generally complains of syncope, dizziness or dim

ness of vision. The relationship to posture may or may not be volunteered. Careful questioning reveals that these symptoms are at their worst in the early morning or in hot weather. In addition to these manifestations, deficiency of the sweating mechanism and polyuria in the recumbent position are often present. The determination of the pulse rate and blood pressure up to eight minutes should never be neglected when postural hypotension is suspected, and whenever possible the examination should be done in the morning and in the standing position. Rational treatment demands appropriate treatment of any organic disease of the nervous system if present, if no such disease is found, the treatment may be medicinal and nonmedicinal. The most effective medicinal agents are the vasoconstrictors, but their effect is only palliative, and they must be used indefinitely unless nonmedicinal measures are successfully employed. Also some patients acquire a tolerance and their use in the elderly with vascular disease is dangerous. Such a patient should be warned against standing immobile for any length of time, but if necessary, he should rise up on his toes from time to time to propel more blood from the lower extremities. Properly fitted abdominal supports are sometimes beneficial. The "head-up" position when sleeping lessens the loss of the adaptive mechanisms gained during the daytime. Dietary measures and graduated exercise warrant a routine trial in all cases.

Phlebography and Thrombosis and Embolism.—Welch and his co-workers state that the phlebogram is not absolutely reliable for the diagnosis of thrombosis. There are many cases in which a leg appears clinically normal while the phlebogram will show a deep thrombosis. However, if clinical signs suggest thrombosis but the phlebogram is indeterminate or negative, thrombosis should be considered to be present and adequate therapy instituted. In general, phlebograms are valuable in any case of known or suspected thrombosis of the veins of the lower leg or after a pulmonary infarct has occurred, unless it arose elsewhere than from the leg. As thrombosis is frequently bilateral, many patients will require bilateral procedures. Superficial thrombophlebitis constitutes a special indication as involvement of the deep system is common in conjunction with thrombosis of the saphenous vein. Systemic manifestations have not occurred after the injection of the 50 cc. of diodrast required for bilateral phlebograms. A contraindication to a phlebogram is sepsis about the ankle. The therapy of venous thrombosis is ligation. Eighty-two femoral veins have been ligated for deep venous thrombosis. Ligation is done for any patient who is 40 or more years of age or, if less than 40, when he has a bland thrombosis or a pulmonary infarct. According to control figures, it should have been expected that about 25 patients would have had further pulmonary infarcts, while 6 would have died if conservative therapy had been employed. However, only

two nonfatal infarcts ensued. Bilateral ligations were done nine times. The site of ligation is important. The vein should be ligated below a large branch to avoid a long static column of blood with potential thrombosis and fatal embolism. Ligatures may be placed on the superficial femoral, common femoral or iliac vessels. Extra dissection required for iliac ligation was avoided by using suction to withdraw thrombi from higher levels. It is advisable to ligate above the thrombosis if possible, if not, over the thrombus using a suction apparatus to extract the clot.

Resuscitation in Advanced Asphyxia.—Advanced asphyxia (cessation of respiration) in dogs was produced by Thompson and Birnbaum by mechanical obstruction of a face mask, obstruction of an intratracheal tube or inhalation of inert gases. The degree of success of the four resuscitation procedures carried out were manual artificial respiration with inhalation of oxygen in 55 per cent, rhythmic inflation with oxygen in 78 per cent, rhythmic suction with oxygen in 80 per cent and rhythmic inflation and suction in 95 per cent.

Interrelationships of Pituitary Gland and Thyroid.—Severinghaus points out that the clinical manifestations of hypothyroidism which are seen in myxedema, pituitary cachexia and anorexia nervosa which involve pituitary and thyroid deficiencies can be separated only by extensive laboratory studies. Yet on physical examination by competent diagnosticians the symptoms are often indistinguishable. Laboratory methods show that the total chemical and physiologic processes of individuals with Simmond's disease differ from those suffering from anorexia nervosa or primary myxedema. Thyroid therapy which dramatically improves the myxedematous condition may cause total collapse and death in the syndromes whose primary lesions are in the pituitary gland. These syndromes are difficult to differentiate because of their close pituitary-thyroid interrelationship. A primary lesion in the thyroid will induce pathologic changes in the pituitary which in turn will be reflected on the entire endocrine system. Thus what started out to be a thyroid deficiency may finally become a pluriglandular syndrome closely resembling total failure of the pituitary gland. One syndrome may merge into another. When a preparation that approaches in value preparations from the thyroid is obtained from the pituitary, many of the perplexing problems of the thyroid-pituitary interrelationship may vanish, at least for the clinician.

Megaloblastic Anemia of Pregnancy and Puerperium—In Edinburgh during the last two years Davidson and his associates had 16 cases of megaloblastic anemia of pregnancy referred to them. Seven were seen prior to the use of liver therapy, but in the remaining 9 such treatment had been used for two days to two months before the authors were called into consultation. The ages, 23 to 41, were considerably lower than those common in Addisonian pernicious anemia. That pernicious anemia of pregnancy occurs mainly in women who have borne several children is not supported by the authors' experience, as 8 of the patients were in their first or second pregnancy. Only 2 patients were seen by them before delivery, but examination of the case records revealed a history of pronounced pallor and dyspnea during pregnancy in 13. In the 8 for whom hemoglobin figures were available they ranged from 18 to 52 per cent and more detailed hematologic data available for 4 indicated a severe anemia of the pernicious type. The anemia became progressively more severe during the last two months of pregnancy. The features serving to differentiate many of the cases from Addisonian pernicious anemia were free hydrochloric acid and a lower frequency and degree of macrocytosis and ovalocytosis. Examination of the sternal marrow before and after liver therapy revealed with 1 exception a picture identical with that found in Addisonian pernicious anemia at equivalent stages and clearly indicated that these anemias have for their immediate cause arrested maturation of the megaloblasts. Accordingly "megaloblastic anemia of pregnancy" is proposed as a substitute for the misleading name "pernicious anemia of pregnancy" on the grounds that the megaloblastic appearance of the bone marrow is characteristic and constant, while the peripheral blood changes are variable. The most acceptable explanation of the anemia is that the primary cause lies in a temporary failure of the gastric secretion of the intrinsic factor of Castle during the later months of pregnancy. Other factors held to be important are a reduced intake of the extrinsic factor, impaired absorption from the small intestine and increased demands by the fetus for the hematimic principles. Ten of the patients were refractory to liver treatment for some time, but with persistent therapy and transfusions they eventually responded. This failure suggests a temporary arrest of erythropoietic function consequent on the absence of some essential factor in addition to the liver principle. A similar state of affairs frequently occurs in sprue. An alternative hypothesis is functional inability of the bone marrow to utilize the various hematimic principles because of the profound strain of pregnancy and the shock of labor occurring in a severely anemic patient. Sepsis probably delayed the response of 6 patients to liver therapy.

Human Isoagglutinin Anti M—Recently, as a result of testing against the erythrocytes of potential donors the serum of a woman who might have needed a transfusion during parturition, Paterson and his associates discovered an antibody,

apparently anti M. No transfusion was given. The woman was 28 years of age and pregnant for the fourth time. Her blood group was ON and she was Rh positive. Serum obtained from her four months after her confinement was tested against the erythrocytes of 20 persons belonging to group O. Undoubted and clearcut agglutination was found in fourteen of the mixtures, all contained the agglutinin M. The six mixtures with no agglutination belonged to group ON and so lacked the antigen M. Although such an occurrence must be exceedingly rare, the case reported shows that its presence may interfere with the selection of suitable blood for a person in whose serum this antibody appears.

Human Fertility—Smith presents data which support the following hypotheses regarding human fertility: (1) If fertilization does not occur, menstruation follows approximately fifteen days after ovulation, (2) within limits there is a "safe" or infertile period a few days before the onset of the next menstrual cycle and (3) an average "safe period" can be predicted with fair accuracy by a sufficiently extended study of the individual's menstrual periodicity. Records of uncontraceptive coitus during thirty-one infertile cycles show that there were occasions when it took place as much as thirteen days before the beginning of the next cycle without ensuing pregnancy. Coitus which took place on the ninth, tenth and thirteenth to sixteenth days after the beginning of a cycle was followed by pregnancy. Prediction of the narrower limits of the fertile period of an individual can be made only by counting back from the beginning of the next cycle. Only the wider limits of the fertile period can be predicted by counting from the beginning of the same cycle, this requires a knowledge of the variation of menstrual periodicity.

Extensive Air Screw Injuries—An example of an extensive but nonfatal injury to the thorax that a revolving air screw inflicts is illustrated by the case reported by Howkins and Wooler in an aircraft apprentice of the Royal Air Force. The injury inflicted during the accident consisted of severe injuries of the right arm and laceration of all three lobes of the right lung. The lung was sutured, the chest was closed without drainage and the right arm was disarticulated at the shoulder joint. A massive infection of the right lung and an apical empyema developed, this was drained and the pulmonary condition resolved. The patient recovered completely and is being considered for retention in the service.

Dementia Precox and Insulin Therapy—In the course of 1937 Quirarte resorted to insulin therapy in 41 cases of dementia precox of different clinical forms and duration. The latter was six months or less in 16 cases in the first group, one year or less in 12 cases in the second group and more than a year and a half in 17 cases in the third group. There were 17 cases of complete remission in the whole group which corresponded to 10 out of 16 cases in the first group, 3 out of 12 in the second group and 4 out of 17 in the third group. Patients with a complete remission were observed for four years by the end of which, in 1941 remission lasted in 10 cases. Three patients had recurrences and are again under neuropsychiatric care. Four had recurrences but carry on a life which is compatible with their stay at home. All the 10 patients with permanent remission are in good physical and mental condition and they work. The author advises application of insulin therapy in dementia precox. The earlier the administration of the therapy the better and more certain the results.

Glutathionemia in Normal Pregnancy and Puerperium J Livio Martini—p 1036
Infantile Paralysis C Goldenberg—p 1042

Mortality in Bronchopneumonia Due to Measles—Bazan and his collaborators observed 33 children from a few weeks after birth to 3 years of age with bronchopneumonia complicating measles. Death from pneumonia took place within the first ten days of the disease. The highest mortality rate was in infants of less than 1 year of age. The majority of children over 3 years of age have recovered. The predominant symptoms of fatal bronchopneumonia due to measles were persistent high fever (over 104.0 F), acute dyspnea and stridor, subacute cyanosis, progressive decline in the general condition, lack of appetite and acute intoxication. Tachycardia was of equal frequency in children who were cured and in those who died. In the latter it was associated with cardiac failure, which did not exist in the former. The pseudolobar form of pneumonia was found in 75 per cent of the patients who died and in 11 per cent of those who were cured. The lack of favorable response to therapy and to baths and especially the failure of blood transfusion in improving the patient's condition constituted important signs of a bad prognosis. As a rule they were not observed in children who were cured. The pathologic anatomy shows not only bronchopulmonary lesions but also multiple lesions, which indicated that the disease is general rather than local. The general condition of the patient before the development of the disease has an influence on the course of the latter. The rate of mortality in bronchopneumonia due to measles is higher for girls than for boys.

Burn from Ensilage Fluid K E Dinesen—p 1434
Container for Feces Specimens O Moltke—p 1435

Treatment of Cerebrospinal Syphilis—Madsen says that lumbar puncture should be made in all cases of syphilis after the ended septicemic period or as a rule from three to six years after the infection. Normal spinal fluid in the latent period seems to exclude later neurosyphilis. If changes in the spinal fluid are found in this period, antisyphilitic treat-

ment is justifiable, but if the spinal fluid does not become normal in the course of some months malaria treatment should be instituted. If signs of cerebrospinal syphilis are already present, for example Argyll Robertson's symptom, a normal spinal fluid does not testify against an active inflammatory process in the nervous system, and in the author's opinion malaria treatment is indicated. A negative Wassermann reaction does not exclude cerebrospinal syphilis. If without demonstrable cause neurasthenic symptoms appear in a previously well man in his prime, the possibility of a beginning paralysis is always to be borne in mind. On the diagnosis of paralysis, malaria treatment as soon as possible is called for, as the duration of the favorable period for treatment is a matter of weeks rather than months. Malaria treatment is regarded as the most effective therapy in dementia paralytica. Four cases treated are reported.

Treatment of Cerebrospinal Syphilis—Lomholt's view is that all forms of recent syphilis in the primary-secondary stage should be given a powerful combined intermittent treatment. In acute syphilitic meningitis the reaction to the treatment is excellent, and the changes in the spinal fluid in the secondary stage usually quickly yield to it. Until proof is available that powerful antisyphilitic treatment can prevent later occurrence of neurosyphilis, he would consider this hypothesis as correct. The few small materials of sufficiently treated cases to date seem to confirm the hypothesis, he says, and practically all syphilologists of consequence agree that paralysis or tabes is rarely seen in a patient who has had a fully effective treatment of his syphilis according to the present day standard. In latent syphilis with changes in the spinal fluid, in which the age of the infection is often unknown, he recommends immediate malaria treatment. To what extent malaria treatment can prevent the occurrence of tabes and paralysis is not certain, because no materials have been observed sufficiently long, but he has not seen any case of tabes or paralysis after malaria treatment of syphilis in the latent stage.

Mortality from Burns Ellen Keller Sprensen—p 1534
Dolantin in Obstinate Hiccups H Jessen—p 1537
Neuralgia Paresthetica Treated Operatively M Ellermann—p 1537

Plasma Prothrombin and Vitamin K in Hepatic Diseases—Bechgaard recommends Quick's method for determination of the prothrombin content of the blood (Lehmann's modification) as easy and reliable for clinical use. Examination by this procedure in 26 cases of liver and biliary tract disorder, he says, showed definite prothrombin reduction in 14. Prothrombin deficiency often occurs in acute hepatitis, cirrhosis of the liver and extensive metastases in the liver, the amount of decrease usually being small (to about 50 per cent), in these cases treatment with vitamin K is not indicated. In grave cases of hepatitis with long-continued acholic feces and during bad periods in cirrhosis a pronounced decrease in the prothrombin content is seen, here vitamin K is indicated, preferably carried out on the basis of determination of the prothrombin content. In cases of bleeding esophageal varices and in all cases of hemorrhage during jaundice it is especially important to determine whether vitamin K deficiency is a contributing cause and to try the effect of treatment with vitamin K.

Gastrointestinal Symptoms in Tumors of Brain—Nielsen found that in 8 out of 25 cases of verified brain tumor gastrointestinal symptoms were the first signs of the brain disorder and dominated the picture until the diagnosis of brain tumor was made. He divides the cases into a dyspepsia group, in which the symptoms are more indefinite, and an ulcer group, in which there are more or less well defined ulcer symptoms. The gastrointestinal symptoms do not afford an indication of the localization of the brain tumor, although most of the tumors had a near relation to the fourth ventricle. Concerning the relation between gastrointestinal ulcer and tumor of the brain, the importance of the neurogenic factor in ulcer pathogenesis in general is emphasized.

Book Notices

The National Formulary National Formulary VII Prepared by the Committee on National Formulary by authority of the American Pharmaceutical Association Official from November 1, 1912. Seventh edition. Fabrikoid. Price \$6. Pp. 690. Washington, D. C. American Pharmaceutical Association, 1942.

The purpose of the National Formulary is to supply formulas for preparations that are in fairly common use within the United States or its possessions and for which formulas are not included in the Pharmacopoeia of the United States, also to provide standards and tests for the identity, quality and purity of the ingredients used in these formulas and for certain other agents enjoying common use.

The seventh edition of the National Formulary contains 459 preparation monographs and 273 monographs on drugs and chemicals. Of these, 97 are new to the National Formulary, among the latter are 71 monographs from U. S. P. XI. The total number of monographs in N. F. VI not admitted to N. F. VII is 51, of which 40 were deleted by reason of their adoption for admission to U. S. P. XII. In addition to improvements in editorial style of the monographs, the National Formulary VII contains an expanded chapter on materials and preparations for diagnostic use and a new chapter on ingredients of reagents and preparations for use in the clinical laboratory. The index, as always, is complete.

This volume which becomes official on November 1, represents the passage of fifty-four years since the first edition appeared in 1888. In each revision there has been an indisputable improvement over its predecessor. The contents of this official organ of the American Pharmaceutical Association follow a style familiar to an untold number of students and followers in a variety of scientific fields and it would be trite to enumerate the chapters. It would be equally unwise to attempt to emphasize the information on reagents, tests and standards which may be found between the covers of this work, but it is impossible to forego the opportunity of saying that this compendium, because of its contents and because of its official nature, should be a "must" in every scientific library, private or otherwise, which is purported to be even moderately up to date.

Chemistry and Physiology of the Vitamins By H. R. Rosenberger. Scd. Cloth. Price \$12. Pp. 674 with 25 illustrations. New York: Interscience Publishers, Inc. 1942.

This monograph is an encyclopedic presentation of the chemistry of the vitamins. The book is well organized and therefore convenient to use. Each of the vitamins is discussed in a chapter which begins with a discussion of nomenclature and a tabulation of the historical development followed by paragraphs on its occurrence and isolation. The main part of each chapter is concerned with the chemical aspects and deals with the procedures used for isolation, proof of chemical constitution and methods of synthesis. There are paragraphs on the determination of each vitamin, with copious references to the literature on the subject. There are also short accounts of the physiologic and pathologic aspects of each vitamin and a section on clinical test methods. There are many valuable tables, such as the list of vitamin D compounds, a table on the relative effectiveness of vitamin D from different sources for rats and chickens, and a table showing compounds having a vitamin K effect. The list of patents pertaining to vitamins which have been issued in the United States and some foreign countries, which appears in the appendix, is unique. The appendix also includes a discussion of the "vitagens," or substances which are similar in some respects to the vitamins. These are the essential fatty acids, the essential amino acids, the essential carbohydrates, choline and related compounds and the labile methyl group, and the essential organic sulfur containing compounds. It is evident that the author prepared this volume with the idea of covering all topics of vitamin research. The selection at times appears to be somewhat arbitrary, especially in the presentation of the historical aspects of the subjects. However, this volume will be valuable for all persons interested in the chemical aspects of the vitamins.

Genetics for Medical Students By F. B. Ford. M. A. B. Sc. Cloth. Price \$8.60. Pp. 162 with 10 illustrations. London: Methuen & Co. Ltd. 1912.

The medical curriculum has long given too little attention to heredity and genetics. This presentation assumes no previous knowledge of the subject and offers the reader a general survey with reference to medicine. The examples are taken primarily from the human being rather than from the fruit fly or the honey bee. The various chapters provide an understanding of the mendelian law of the genes and the blood groups. The explanations are so simple that medical students should be able to follow them with little difficulty. Especially valuable is the section on the detection of inherited characters. Here is a conspicuous example of the author's style and rationality.

The question of eugenic reform encroaches upon one of the special preserves of the fanatic, the problem of Race. To some in these days it has become a creed that such concepts as the British, the Nordic or the Jewish races have or have not reality. In this matter as in many others extreme views appear to be incorrect.

On the one hand it is not admissible to maintain that such races are purely artificial. Their characters have some reality and we have good evidence that they may be preserved when one people is immersed among others. It has already been mentioned that the blood group frequencies of Dutch and Russian Jews are much more alike than are those of the communities among whom they live. On the other hand, particulate inheritance allows the maintenance within each race of vast reserves of variability capable of producing, without racial mixture, far greater diversity than that separating any of them. Recurrent mutation allows the gene of one race to appear in another and a great part of their gene complex have even the most diverse of the human races in common. That no shadow of specific distinction can be detected even between the most dissimilar of them. The proportion of genetic material which is different in the more nearly allied races cannot be great.

An appendix offers new information regarding cytology and a classified list of inherited characters and a good working bibliography.

The Art of Self Control How to Make Your Habits Work for You By Ralph A. Haber. Cloth. Price \$2. Pp. 264. New York: Reynal & Hitchcock, 1941.

This is another of those books which are supposed to help people adjust better to the problems of life. It is not as bad as some and not as good as others. The author has taken a number of accepted unaccepted and partially accepted beliefs of psychologists and presented them in such a way that they make interesting reading, give plausible explanations of rather superficial mental reactions and stimulate the person who is a little inquisitive to do something about his problems. The author stresses habit correction, self control, the improvement of one's habits and other common psychological problems. The examples that he cites are largely popular in nature and the persons whom he quotes run the gamut from Benjamin Franklin to Eddie Cantor. The clinical psychologist is very skeptical about changing unfortunate habits or weak systems of thought without careful study relative to how the problem has arisen and without directing specific psychiatric tests to the cause and to the complicating features of each person's problems. For that reason it would seem almost impossible for any one to get his money's worth out of "The Art of Self Control." The normal person with some feelings of inadequacy will get little out of the book, the abnormal person who is groping for something to aid him and who is trying to avoid going to the physician will probably put it to some bizarre use. It must be admitted, however, that much of the psychology in it is currently accepted although the acceptance arises from the fact that the lay observer can recognize the psychological trait. It does not go into the root causes of maladjustment or inadequacy.

Journal of Proceedings and Addresses of the Forty Third Annual Conference The Association of American Universities Held at the University of Nebraska October 30-31 and November 1, 1941. Paper. Pp. 114. Chicago: University of Chicago Press [n. d.].

The report of this conference which was held at the University of Nebraska, Oct. 30-Nov. 1, 1941, contains discussions of many of the current problems facing the institutions of higher learning of this country. The universities are prepared to undertake their part in improving Latin American relations and have authorized their committee in this field "to investigate perhaps with the aid of the United States Office of Education the problem of classifying and accrediting Latin American institutions of higher learning." Resolutions adopted by the association indicate the seriousness of the problems the univer-

sities are called on to face in connection with their efforts to maintain adequate personnel for teaching and research in the face of the demands of industry and government service. In the report are published the addresses given at the conference, several of which were by government officials. The subjects include "Social Security and Higher Education," "The Role of the University in the National Defense Program" by General Lewis B. Hershey, "American Education and Naval Requirements" by Admiral Chester W. Nimitz and a symposium on "University Procedures and Problems Growing out of Defense Activities."

The Education of Children in Hospitals and Convalescent Homes. The Committee for the Study of the Care and Education of Physically Handicapped Children in the Public Schools of the City of New York. Report of the Sub Committee on the Education of Children in Hospitals and Convalescent Homes. Paper. Pp 57. New York: Board of Education 1941.

Children with Speech Defects. The Committee for the Study of the Care and Education of Physically Handicapped Children in the Public Schools of the City of New York. Report of the Sub Committee on Children with Speech Defects. Paper. Pp 61. New York: Board of Education 1941.

These studies were made by subcommittees on the education of children in hospitals and convalescent homes, a subsidiary of a larger committee for the study of the care and education of physically handicapped children in the public schools of the city of New York.

The booklet on education of children in hospitals consists of a historical consideration of efforts to continue the education of children confined in hospitals and related institutions, followed by a study of medical relationships to the educational process, a survey of the educational process itself, reports of teachers engaged in the teaching of children in institutions, a discussion of all the facts presented by the committee, and recommendations.

In brief, the committee finds that with few exceptions physical equipment is satisfactory but that the educational process is not carried out at the fullest efficiency nor is there satisfactory coordination and understanding between physicians responsible for the care of children with chronic illness and teachers responsible for their educational progress. The recommendations, in brief, are as follows:

(a) That the institution have continuously sufficient children able to profit from instruction and that it furnish suitable conditions for instruction.

(b) Instruction for daily periods of less than one hour for less than one month is of doubtful value that children be taught only on the recommendation of a physician that adequate information concerning the physical condition and ability of the pupils be provided for the teacher.

(c) That occupational and recreational therapy as distinguished from education is not or should not be the primary purpose of the department of education.

(d) That within its physical limitations a child's educational program conform to the prevailing program in the public schools that bedside instruction be given only where it will be educationally profitable and whenever possible in groups.

(e) That psychological services of the institutions be more generally utilized for the benefit of children and teachers.

(f) That home instruction where necessary should follow hospitalization that pupils discharged from hospitals and institutions be promptly admitted to school or special classes.

(g) That chronic cases requiring long hospitalization should be given high school training as their needs indicate.

The second booklet is by another subcommittee on children with speech defects. This report likewise consists of a historical review, a summary of procedures and studies, and a summary of findings plus recommendations. The principal recommendations of medical interest are six out of twenty-one recommendations as follows:

1 That children with severe organic and functional speech disorders be referred to hospital and educational clinics for treatment.

2 That each child selected for speech correction be given a general medical examination by the school physician.

3 That the school physician refer the child to appropriate specialists for special examinations when deemed necessary.

4 That records of medical examinations be made available to the speech correctionists.

5 That adequate psychiatric and psychological social work be made available for speech handicapped children.

6 That the Board of Education urge on the hospitals the need for special clinics.

These monographs are primarily of interest to school physicians and pediatricians.

Family Nutrition. Published by the Philadelphia Child Health Society. Paper. Pp 106 with illustrations. Philadelphia 1942.

The authors of this little monograph of the Philadelphia Child Health Society recognize that adequate nutrition is largely a family problem and that suggestions about the purchase of foods had best apply to family groups. The monograph shows how the nutritional status of human beings may be measured, discusses the nutrients which are needed and describes the contribution which foods can make to supply the needed nutrients. There are brief discussions of appetite and of feeding problems and of nutrition in relation to resistance to disease. It is shown how people in different income groups can still make good dietary selections though their purchasing power may be low. The book is well illustrated and documented. A considerable portion of the pamphlet is devoted to the selection of foods for persons of different ages. An interesting item is the suggestion that plenty of butter be used on bread and on vegetables, 2 to 3 ounces daily is considered desirable for boys and girls 6 to 12 years of age. There are of course other views, some authors hold the opinion that butter is best consumed by children in the form of milk. A considerable number of recipes for foods listed under the food stamp plan are given. Because this is published by the Philadelphia Child Health Society it is perhaps to be expected that recipes for scrapple and for pork and parsnip stew would be provided. The tables for nutritionally adequate meals for families with different incomes should be exceedingly useful. Altogether this monograph is crammed with the kind of information people will need to have if they are to be guided in their selection of foods by the advances in nutritional science.

Volumetric Analysis. By I. M. Kolthoff, Professor and Head of Division of Analytical Chemistry, University of Minnesota, Minneapolis, and V. A. Stenger, Analytical Research Chemist, The Dow Chemical Company, Midland, Mich. Volume I: Theoretical Fundamentals. Second edition. Cloth. Price \$4.50. Pp 309 with 31 illustrations. New York: Interscience Publishers, Inc. 1942.

In accordance with the couplet

The theory guides
The experiment decides

this book is divided into two volumes, the first of which includes the theoretical treatment of volumetric chemical analysis. The first edition of volume I appeared in German in 1927 and was translated into English in 1928. A second German edition appeared in 1930, and this present work is an enlargement and revision of these predecessors. In keeping with the increasing use of volumetric reactions, the section on oxidation-reduction reactions has been extended, the list of oxidation potentials brought up to date, chapters on catalysis and induced reactions and on adsorption and coprecipitation phenomena have been completely revamped and a discussion of mixed crystal formation added. The influence of the authors' interest in polarography may be seen in the addition of a chapter on amperometric methods of analysis. One subject that could well have been included is a discussion of titration of azo dyestuffs. The volume is one of the most complete of its kind and may be used as a text or reference book. The theoretical discussions of such subjects as interfering substances, hydrolysis, precipitation reactions and effect of hydrogen ion concentration are accompanied by mathematical proof and methods of calculating errors and results. This makes the text more understandable and readable. This volume may be considered as a prerequisite to the use of volume II by students and laboratory technicians alike and should also prove invaluable to the teacher.

Food and Beverage Analyses. By Milton Arlenden Bridges, B.S., M.D., F.A.C.P., Consulting Physician, Seaview Hospital, Staten Island, New York, and Marjorie R. Mattice, A.B., M.S., Assistant Professor of Pathological Chemistry, Department of Medicine, New York Post Graduate Medical School, Columbia University, New York. Second edition. Fabrikoid. Price \$4. Pp 344. Philadelphia: Lea & Febiger, 1942.

The second edition of this excellent compilation of information about foods contains a revision of the original extensive list of food values and many new tables. The latter provide information about the hydrogen ion concentration of foods, their fiber content and the amount of sulfur, bromine, calcium, oxalate, phytins and purines contained in them. There are also new tables of the percentages of available carbohydrate and ionogenic iron in foods. The material is in a readily use-

ful form and there is a suitable bibliography. All these features make this one of the most complete single sources of information available on the composition of foods.

Among the most surprising facts that have been noticed in the present volume are the following items. Dandelion greens are said to contain as much as 6 mg of iron in each hundred grams of fresh edible substance. Red carrots contain the surprisingly high amount of 8 per cent fiber. Fried cod roe contains 112 mg of purine nitrogen in each hundred grams, whereas caviar is said to contain none. This would seem to be in error, because caviar certainly must contain considerable nuclear material. Roast duck contains 395 mg of sulfur in each hundred grams, which is higher than the sulfur content of shrimp and all other foods with the exception of whelks, mustard and dried carrageen moss. Cod liver oil contains about 7,000 parts per billion of iodine, which means that a teaspoon of this beverage contains about as much iodine as there would be in a third of a gram of iodized salt. It is also stated in the book that the composition and fuel values of mixed alcoholic beverages vary greatly and are not susceptible of reliable analytical presentation.

Vitamins for Health. By Henry Borsook and William Huse. California Institute of Technology, Pasadena. Public Affairs Pamphlets No. 69. Paper. Price 10 cents. Pp. 32. New York: Public Affairs Committee, Inc. 1942.

This well written pamphlet is intended for persons who are looking for an easy guide to the use of vitamins, and hence it is directed to the public rather than to the medical profession. It fails somewhat in being as good as it should be for enthusiastic recommendation. While there are many items of value and much common sense is displayed in the selection of facts, there are some statements which could well be eliminated from a pamphlet of this sort. For example, it is stated that meat should not be fried for children. Certainly there is no valid reason why fried meat is not just as useful as roasted meat or stewed meat, indeed, there is evidence that frying meat is less destructive of thiamine than cooking by any other means. It is also asserted that a daily quart of vitamin D milk would not provide children with as much of this vitamin as they need, there is much evidence that milk containing 400 U. S. P. units of vitamin D to the quart is sufficient. It is stated that from 20 to 30 per cent of the thiamine content of flour is lost in baking, the better evidence indicates that the loss is only about 10 per cent in the baking of bread, most of this loss occurring in the crust and little in the inside of the loaf.

The emphasis of the book, of course, is on the vitamins, but it might be well if the authors called attention to some of the other factors, such as calcium, which also are important in the diet. The general effect of the pamphlet no doubt will be to encourage the use of vitamin preparations, which is perhaps anticipated by the inclusion of a number of hints for vitamin buying. There may be some justification to the point that persons who obtain most of their meals in restaurants and cafeterias where food is kept warm for hours, exposed on steam tables, do not obtain the vitamins they think they do from the vegetables which they eat. Here the remedy should be not to eat vitamin pills but to correct the underlying difficulties, if they do exist. It is doubtful that one could follow the instructions of the authors and select vitamin preparations wisely. Further, the authors have included no discussion in their pamphlet of labeling provisions for such preparations, as now required by regulations of the Food and Drug Administration, and their interpretations.

Memorable Days in Medicine. A Calendar of Biology and Medicine. By Paul F. Clark and Allee Sehlstedt Clark. Cloth. Price \$2. Pp. 305 with 29 illustrations. Madison: University of Wisconsin Press, 1942.

Many a chronology has been published of important dates in medicine. Such collections reflect the special interests of their authors. This book is a collection of dates that should be of interest to students in the fields of medicine and biology. For instance, on Aug. 25, 1841 Theodor Kocher was born in Switzerland, on Aug. 25, 1867 Michael Faraday died. Notes regarding each of the events cited are exceedingly brief and

the interest of many of them remote. Any one interested in the historical aspects of science, however, will find study of these notes stimulating for further reading. An occasional medical anecdote helps to enliven the text.

The Meat You Eat. Report of the New York State Trichinosis Commission. Legislative Document No. 35, 1942. Paper. Pp. 141. New York, 1942.

The New York State Trichinosis Commission was created in 1940 and extended in 1941 for the purpose of studying and recommending methods of curbing trichinosis and other diseases contracted by eating infected meat. This book, the report of that commission, embodies a brief history of trichinosis, the present status of the disease and a chapter on trichinosis developments during 1941 by Dr. Willard H. Wright, chief of the Division of Zoology, National Institute of Health, United States Public Health Service. Much of the report deals with the value of meat and the status of meat inspection. The commission recommends that the state adopt a statewide compulsory meat inspection administered by local governments. A footnote states that this recommendation has just been approved. Previous recommendations of the commission were to the effect that slaughterhouses be maintained in a sanitary condition and licensed by the state that intrastate pork products customarily eaten without cooking be processed to destroy live trichinae, that mixing of pork in hamburgers be barred and that uncooked offal from slaughterhouses be outlawed for feeding purposes. These were adopted in 1941. This report constitutes a useful contribution to the attack on trichinosis.

First Official List of Books, Pamphlets, Posters, Charts and Periodicals on Food and Nutrition. Compiled by the Technical Committee on Evaluation of Printed Material, New York City Nutrition Program. Paper. Price 15 cents. Pp. 23. New York, 1942.

Frequently it is desirable to have posters or educational material about foods and nutrition and it is difficult to find just what one wants. Now the Technical Committee on the Evaluation of Printed Material of the New York City Nutrition Program has made a list of books, pamphlets, posters, charts and periodicals on foods and nutrition. The material is listed on twenty-three mimeographed pages. The selection is excellent and includes not only books and other material that are on the market but also material that is obtainable without charge. A few notations accompany the listing of some of the material. This compilation should be most valuable for all those who are asked about good books on nutrition or of available posters or charts on vitamins or on milk, meat, fruits, vegetables or other foods. The only drawback, perhaps, is that the list may appear to be too formidable to encourage the selection of a few items for careful study.

Wartime Meals. How to Plan Them. How to Buy Them. How to Cook Them. By Margot Murphy [Jane Holt]. Food Editor, New York Times. Cloth. Price \$2. Pp. 215. New York: Greenberg Publishers, Inc. 1940.

Now there is much interest in wartime meals and in possible shortages of and substitutes for foods. The author, who contributes a food column to the New York Times under the name of Jane Holt, has compiled an interesting volume. An important feature is the collection of recipes which make use of products that are economical and readily obtainable under present conditions. The book is a cook book blended with a guide to buying the least expensive foods and containing a dash of nutrition.

The Clarks. An American Phenomenon. By William D. Mangum. With an introduction by Edward Alsworth Ross, Professor of Sociology, University of Wisconsin. Madison. Cloth. Price \$2.50. Pp. 201 with 12 illustrations. New York: Silver Bow Press, 1941.

While this study may claim to be "one of the most amazing stories of American economy and life," it is primarily a sociological record with but little of medical concern. It undoubtedly illustrates an unpleasant but important phase of American sociological and economic history in the past century. The career of William Andrews Clark, self made copper king, at one time "one of the richest men in the world," U. S. Senator from Montana, is typical of many ingenious, able, unscrupulous Western pioneers, overcredulous as to what money could buy. The fate and shortcomings of his sons and daughters occupy the remainder of a poorly told and poorly presented sordid tale.

ful form and there is a suitable bibliography. All these features make this one of the most complete single sources of information available on the composition of foods.

Among the most surprising facts that have been noticed in the present volume are the following items. Dandelion greens are said to contain as much as 6 mg. of iron in each hundred grams of fresh edible substance. Red carrots contain the surprisingly high amount of 8 per cent fiber. The book is a cook book blended with a guide to buying the least expensive foods and containing a dash of nutrition.

The Clarks: An American Phenomenon. By William D. Mangum. With an introduction by Edward Alsworth Ross, Professor of Sociology, University of Wisconsin, Madison. Cloth. Price \$2.00. Pp. 251 with 12 illustrations. New York: Silver Bow Press, 1941.

While this study may claim to be "one of the most amazing stories of American economy and life," it is primarily a sociological record with but little of medical concern. It undoubtedly illustrates an unpleasant but important phase of American sociological and economic history in the past century. The career of William Andrews Clark, self-made copper king, at one time "one of the richest men in the world," U. S. Senator from Montana, is typical of many ingenious, able, unscrupulous Western pioneers, overcredulous as to what money could buy. The fate and shortcomings of his sons and daughters occupy the remainder of a poorly told and poorly presented, sordid tale.

MENTAL AND NERVOUS EFFECTS OF
LIGHTNING SHOCK

To the Editor—A patient in this hospital was struck in the head by lightning two years ago and has gradually become psychotic since that time. His Wassermann and spinal tests have been negative but neurologically he shows an abnormal Romberg sign. Roentgenograms of his head reveal no apparent damage. The staff of the hospital suspects some neuron degeneration. I would be grateful to you for any information on this subject.

J J Johnson Jr, MD Las Vegas N M

ANSWER—Being struck by lightning is essentially the same as being shocked by other types of strong electric current. In lightning the atmosphere acts as a conductor. Clinical manifestations involving the central nervous system range from mild concussion of the brain to fatal electrocution. When lightning strikes the head the damage usually is considered to be more transient than in electric shocks from other sources and of comparable intensity. However, owing to the grounding of both feet, involvement of the spinal cord is more frequent in lightning. Persons so struck also are often thrown into the air and fall down at some distance, thus sometimes suffering an additional trauma to the head which is often overlooked.

Some of the pathologic changes observed in the brain are considered to be specific for this type of accident by a number of authors. All elements of the brain, including ganglion cells, glial substance, meninges and blood vessels, may be involved. Chromatolysis, particularly in the cells of the medullary nuclei and of the Purkinje cells of the cerebellum, is frequent. The tunics of the larger blood vessels, particularly the membrana elastica, are often damaged. Around the smaller vessels perivascular shrinkage is a frequent finding. In the more deeply situated parts of the brain the ganglion cells succumb more easily than the glia. The meninges may react diffusely.

Accordingly the neurologic findings in such cases are extremely variable. Frequently the clinical symptoms are isolated and merely evidence of damage in some part of the brain. But the consequences of electrical accidents have been observed to simulate systemic neurologic diseases although at times the trauma may act merely as the precipitating or aggravating factor in making a preexistent disease clinically evident. Arteriosclerotic brains are said to be most easily and most severely affected by electrical accidents.

As to mental conditions it is unfortunate that the type of psychotic behavior displayed by this patient is not indicated. In industrial electrical accidents involving the head psychoneurotic reactions are frequent, ranging from mild traumatic neuroses to cases of full-blown hysteria, but they have rarely, if at all, been observed following lightning. Behavior disturbances with loss of inhibition has been observed in children struck by lightning. Also a few cases of acute delirious state with hallucinosis, of short duration, have been described. However, the most frequent mental syndrome following such accidents is a psychosis closely resembling dementia paralytica. Gradual intellectual deterioration, and even complete dementia, changes in personality, grandiose ideas, intermittent hypochondriacal or depressive states, and occasional hallucinations have been noted in these cases of so called pseudo-dementia paralytica. Tremors, speech and pupillary disturbances, even signs of dementia paralytica with tabes, may be present. Care, however, should be taken to rule out a true dementia paralytica with negative serologic reaction, particularly in view of the predilection of this disease for becoming clinically manifest following traumatic head injuries. In this connection it should also be remembered that a schizophrenic or other type of mental disorder may have preexisted and simply been precipitated by the lightning accident or the accompanying fall.

The prognosis in the case in question in view of the onset duration and presumable organic damage appears rather poor. Treatment should be expectant and symptomatic. Shock therapy of any type appears contraindicated in this case.

DEATH FROM ILLUMINATING GAS

To the Editor—A woman was found lying on the floor in her kitchen dead. The gas jets were wide open and a window and a door to the room were also open. The pathologist who performed the autopsy says the evidence indicates that death was by gas poisoning. The person accused of the crime admits binding the woman's hands and feet and leaving her lying on the floor but claims to know nothing about the gas. The defense lawyers wish to claim that gas was inhaled before the assault and that it would be impossible for a person lying on the floor to inhale enough gas to cause death when a window and door to the room are open. Is this true or does not gas being heavier than air sink to the floor?

J Street Brewer MD, Roseboro N C

ANSWER—Death from illuminating gas can be established by a quantitative test for carboxyhemoglobin in the blood. Concentrations of 30 per cent or over indicate death by carbon monoxide. Without this test an opinion would be purely conjectural and would require further information. For example: 1 Did the necropsy reveal a cherry red color of the blood and organs and was the postmortem lividity cherry red in color? 2 How many gas jets were open? 3 What were the dimensions of the room? 4 How far was the body found from the open gas jets? 5 Was there an opportunity for a draft through the room? 6 What were the meteorological conditions on the day of death?

From the facts submitted it would be impossible to express an opinion whether the assault was perpetrated after the inhalation of gas. In any circumstances this would be a difficult matter. However, it is difficult to conceive that an assailant would bind a woman's hands and feet, turn on the gas and return later for the assault. If the gas permeated the room in sufficient concentration to kill the victim the assailant would certainly become asphyxiated if he remained.

While illuminant gas is slightly lighter than air, it could accumulate and has accumulated in rooms with windows and doors open in sufficient quantities to kill an inmate.

MASSIVE EDEMA OF FEET AND ANKLES OF
UNDETERMINED CAUSE

To the Editor—A white woman aged 42 has a massive edema of the feet and ankles. The cardiac blood and urinary findings are negative. The edema is periodic and the swelling is usually occasioned by hot weather. Sometimes the swelling subsides almost entirely during the night but when she arises and after pursuing her daily routine for several hours the feet and ankles again swell to enormous proportions. There is no redness and little or no pain but great discomfort and embarrassment. Could this be an incipient erythromelalgia? These conditions have obtained for several years. Would you please suggest a proper regimen? Any other information will be appreciated.

James A Laird MD Chicago

ANSWER—As a general proposition the initial symptom of erythromelalgia is pain. The pain is succeeded by redness and swelling, but the swelling does not usually assume massive proportions. The fact that there is no disease of the circulation or kidney would point toward a local cause. Swelling of the extremities in hot weather is not uncommon in those who have congenitally deficient veins and in varicose veins. Such swelling does not assume massive proportions, however, unless the varicose veins are quite evident. One should next consider obstruction to the venous or lymphatic flow. Tumors of the pelvis and old thrombophlebitis of the pelvic veins are leading causes of such obstruction. An old lymphadenitis is a possible but not probable cause. Parasitic infestation of the lymph spaces must be considered.

Until the cause can be discovered, a definite plan of treatment is difficult to prescribe. In general the weight should be reduced if there is any tendency to overweight. The feet should be kept elevated at every opportunity and some sort of additional support should be given to the circulation. An elastic or mesh stocking should be applied while the swelling is absent. This support should extend from the tips of the toes to well above the knee. While this will not remove the cause of the swelling, it will certainly improve the esthetic effect and remove some of the embarrassment.

STERILIZATION OF BITCHES BY X RAYS

To the Editor—Is it practicable to sterilize female dogs by means of high voltage roentgen therapy? I realize that ovulation is brought about by mating while heat is the result of endocrine stimulation. If it is possible to inactivate the ovaries will the animal still have estrus?

M D Pennsylvania

ANSWER—Veterinarians do not consider it practical to sterilize female dogs by means of high voltage roentgen therapy. In a few cases bitches have been sterilized by this method and estrus was inhibited. When all ovarian tissue is removed surgically as this is usually done in veterinary practice, estrus always ceases.

losis. They point out that the histologic structures of the sarcoids can be distinguished from that of genuine tuberculosis, caseous necrosis is absent, and in their experience tubercle bacilli have never been found by staining, culture or inoculation, that there is no tuberculin reaction in many cases with sarcoid, whereas there is nearly always a reaction in the presence of tuberculosis. Moreover, they call attention to necropsies on persons who have died of sarcoidosis which have revealed no evidence whatever of tuberculosis. Even inoculation of animals with necropsy material proved negative. These authors conclude that it must therefore be considered as a peculiar reaction of the reticuloendothelium with formation of pseudotubercles under influence of an unknown virus.

The symptoms of sarcoidosis closely resemble those of tuberculosis and, in fact, may be identical. When there is general dissemination of the sarcoids throughout the lungs, x-ray shadows may appear identical with those seen in military tuberculosis. Indeed, many cases have been diagnosed as military tuberculosis on the basis of x-ray shadows.

Sarcoids tend to undergo fibrotic degeneration and may be completely replaced by connective tissue. When this is disseminated throughout the lungs, the x-ray leaves evidence of chronic fibrosis which is practically identical with that seen in chronic fibroid tuberculosis. Indeed the lesions in the lung may cast shadows which do not differ materially from those found in chronic tuberculosis, silicosis, lymphogranuloma disseminatum, pneumonia and military carcinoma.

In the differential diagnosis the intracutaneous tuberculin test may be of great importance. Indeed, if there is no reaction it is almost certain that tuberculosis does not exist. Moreover in cases of sarcoidosis tubercle bacilli cannot be found in the sputum, in gastric washings or in biopsies. When a tuberculin reaction is present, as is true in some cases of the disease, one does not have evidence that the demonstrable lesions are cast by tuberculosis, since primary tuberculosis may also exist and this always results in sensitivity to tuberculin. Therefore by most careful clinical examination one is not able to make more than a tentative diagnosis of sarcoidosis. It is only by microscopic examination of the lesions taken from the skin or involved lymph nodes near the surface of the body and the absence of tubercle bacilli in them that a certain diagnosis is possible during life.

There is no specific treatment for sarcoidosis. On an entirely empirical basis numerous treatments have been used, such as general hygienic and dietetic care, subcutaneous injections of gold, chaulmoogra oil and enlarged doses of vitamin C. However these have not been proved to be of definite value. Bock found that cutaneous sarcoids respond favorably to the administration of arsenic. Therefore this drug may be used to advantage in moderate or large doses even up to 30 mg of arsenic trioxide administered subcutaneously daily.

Usually the prognosis is good. Even patients who have sarcoidosis with extensive involvement of the lungs pronounced enlargement of the lymph nodes, the liver and spleen and numerous sarcoids of the skin recover so completely that evidence of lesions can no longer be found in any part of the body by present methods of examination during life. However, some patients do not recover. For example there may be so much fibrous degeneration in the lungs resulting in extensive sclerosis that insufficiency of the right ventricle occurs.

OXYGEN CONSUMPTION OF BRAIN DURING ANESTHESIA

To the Editor—An abstract in The Journal April 11 1942 page 1324 of a paper presented before the Central Society for Clinical Research in November 1941 by John L. Lundquist and George V. Leroy raises a question in my mind. Has the technique set forth there or any other been employed to determine whether potent anesthetics e.g. cyclopropane especially allowing the use of high oxygen concentrations really do permit high oxygen utilization or actually decrease the ability of the brain and other vital tissues to utilize oxygen? In other words reversibly to a certain point do they throw 'out of balance' the intracellular oxygenase? As far as is known has this point been investigated on relatively intact tissues (not minced brain tissue as employed by numerous investigations)?

Dell T. Lundquist M.D. Palo Alto Calif

ANSWER—A review of the literature reveals no studies on the oxygen consumption of the intact brain during cyclopropane anesthesia. The question as to whether or not narcotized tissues are better able to utilize oxygen when it is available in higher concentrations is important, but the theory that the mechanism of narcosis depends on inhibition of the oxidative activity of nerve cells is only one of several views. The depression of cellular metabolism during anesthesia may be a result rather than a cause of narcosis. The work of Lennox and Gibbs indicates that an unconscious state, such as epilepsy, may occur even

though oxygen is freely available and further that within certain limits the oxygen consumption of tissues is unaltered by changes in the oxygen tension of the blood.

Studies on the effects of various anesthetics on brain metabolism have hitherto been largely confined to in vitro measurements of oxygen consumption by minced brain tissue or slices. Handley and his co-workers made studies on intact animals but did not control the factor of blood flow. In their perfusion experiments they demonstrated a measurable reduction in oxygen and dextrose utilization with soluble pentobarbital depression and a return to normal or beyond with metrazol stimulation. Bulow and Holmes have stated that the oxygen uptake of minced brain tissue is not affected by the presence of anesthetic gases such as nitrous oxide and acetylene, but it has been clearly shown that a number of anesthetics cause a diminution in oxygen uptake by brain tissue. There are, as the question implies, several serious objections to the study of oxygen consumption using traumatized or minced brain tissue. A study of cerebral oxygen consumption during cyclopropane anesthesia in the intact animal would be of definite value.

RECURRENT PHLEBITIS

To the Editor—A man aged 54, whom I first saw in August 1938 dated the beginning of his ill health to the year 1932. Previous to that time he stated he had rarely had a sick day. In 1932 he had a severe case of furunculosis. Ever since however, he has been susceptible to staphylococcal infections. Cuts and scratches develop up rapidly and he has a bad infection. There are three boils at the present time—one on the right elbow, one on the right forearm and right leg. In 1935 he began to have trouble with his prostate. In 1940 he had a transurethral resection by fulguration. The diagnosis was simple hypertrophy. During his convalescence from this operation although some five or six weeks later, he developed phlebitis of the left arm and right leg in the superficial veins. Simultaneously in 1941 he developed bronchopneumonia and phlebitis of the deep vessels of the right leg. Recovery was slow, taking about twelve weeks. In June 1942 phlebitis of the superficial veins of the left leg developed and is responding slowly. I have tried many lines of investigation. The diet has been corrected, the free fluid intake is satisfactory. As far as possible the hygiene of the home has been corrected. The teeth have been checked repeatedly for infection, the tonsils have been extracted, apparently the appendix and gallbladder are normal, constipation has been corrected as well as possible. Aside from the phlebitis the physical examination is negative, the renal function and urinalysis are also negative. The blood chemistry and counts are normal. The blood cultures are negative.

M.D., Virginia

ANSWER—The problem of prevention of recurrence of phlebitis is frequently complicated and cannot be solved satisfactorily. Examination of the status of the patient's peripheral arterial circulation should be made, since recurrent phlebitis is commonly a manifestation of thromboangiitis obliterans. Also when phlebitis affects recurrently a man older than 50 one should think of the possibility of carcinoma, since intra-abdominal and intrathoracic carcinoma are frequently associated with recurrent phlebitis. Blood dyscrasias which favor thrombophlebitis have presumably been excluded. One should pay particular attention to the possibility of polycythemia, which notoriously provokes thrombophlebitis. If careful reconsideration discloses no primary condition of which the thrombophlebitis might be a secondary manifestation, it becomes necessary to proceed hopefully with measures which lack specificity. Superficial, inflamed veins should be removed and cultures taken. If organisms are found, vaccine may be made and administered. The patient should stop smoking. The intermittent administration of some of the sulfonamide compounds may help. If trichophytosis is present, it should be treated vigorously. If thrombophlebitis continues to recur, prolonged treatment with the new anticoagulant substance dicoumarol may be advisable, although the administration of this substance is used chiefly in instances of thrombophlebitis in which the recurrences are close together.

MENTAL AND NERVOUS EFFECTS OF
LIGHTNING SHOCK

To the Editor—A patient in this hospital was struck in the head by lightning two years ago and has gradually become psychotic since that time. His Wassermann and spinal tests have been negative, but neurologically he shows an abnormal Romberg sign. Roentgenograms of his head reveal no apparent damage. The staff of the hospital suspects some neuron degeneration. I would be grateful to you for any information on this subject.

J J Johnson Jr, MD Las Vegas N M

ANSWER—Being struck by lightning is essentially the same as being shocked by other types of strong electric current. In lightning the atmosphere acts as a conductor. Clinical manifestations involving the central nervous system range from mild concussion of the brain to fatal electrocution. When lightning strikes the head the damage usually is considered to be more transient than in electric shocks from other sources and of comparable intensity. However, owing to the grounding of both feet, involvement of the spinal cord is more frequent in lightning. Persons so struck also are often thrown into the air and fall down at some distance, thus sometimes suffering an additional trauma to the head which is often overlooked.

Some of the pathologic changes observed in the brain are considered to be specific for this type of accident by a number of authors. All elements of the brain, including ganglion cells, glial substance, meninges and blood vessels, may be involved. Chromatolysis, particularly in the cells of the medullary nuclei and of the Purkinje cells of the cerebellum, is frequent. The tunics of the larger blood vessels, particularly the membrana elastica, are often damaged. Around the smaller vessels perivascular shrinkage is a frequent finding. In the more deeply situated parts of the brain the ganglion cells succumb more easily than the glia. The meninges may react diffusely.

Accordingly, the neurologic findings in such cases are extremely variable. Frequently the clinical symptoms are isolated and merely evidence of damage in some part of the brain. But the consequences of electrical accidents have been observed to simulate systemic neurologic diseases, although at times the trauma may act merely as the precipitating or aggravating factor in making a preexistent disease clinically evident. Arteriosclerotic brains are said to be most easily and most severely affected by electrical accidents.

As to mental conditions, it is unfortunate that the type of psychotic behavior displayed by this patient is not indicated. In industrial electrical accidents involving the head psychoneurotic reactions are frequent ranging from mild traumatic neuroses to cases of fullblown hysteria but they have rarely, if at all, been observed following lightning. Behavior disturbances with loss of inhibition has been observed in children struck by lightning. Also a few cases of acute delirious state with hallucinosis, of short duration, have been described. However, the most frequent mental syndrome following such accidents is a psychosis closely resembling dementia paralytica. Gradual intellectual deterioration, and even complete dementia, changes in personality, grandiose ideas, intermittent hypochondriacal or depressive states, and occasional hallucinations have been noted in these cases of so called pseudo-dementia paralytica. Tremors, speech and pupillary disturbances, even signs of dementia paralytica with tabes, may be present. Care however, should be taken to rule out a true dementia paralytica with negative serologic reaction, particularly in view of the predilection of this disease for becoming clinically manifest following traumatic head injuries. In this connection it should also be remembered that a schizophrenic or other type of mental disorder may have preexisted and simply been precipitated by the lightning accident or the accompanying fall.

The prognosis in the case in question in view of the onset duration and presumable organic damage appears rather poor. Treatment should be expectant and symptomatic shock therapy of any type appears contraindicated in this case.

DEATH FROM ILLUMINATING GAS

To the Editor—A woman was found lying on the floor in her kitchen dead. The gas jets were wide open and a window and a door to the room were also open. The pathologist who performed the autopsy says the evidence indicates that death was by gas poisoning. The person accused of the crime admits binding the woman's hands and feet and leaving her lying on the floor but claims to know nothing about the gas. The defense lawyers wish to claim that gas was inhaled before the assault and that it would be impossible for a person lying on the floor to inhale enough gas to cause death when a window and door to the room are open. Is this true or does not gas being heavier than air sink to the floor?

J Street Brewer MD Roseboro N C

ANSWER—Death from illuminating gas can be established by a quantitative test for carboxyhemoglobin in the blood. Concentrations of 30 per cent or over indicate death by carbon monoxide. Without this test an opinion would be purely conjectural and would require further information. For example: 1 Did the necropsy reveal a cherry red color of the blood and organs and was the postmortem lividity cherry red in color? 2 How many gas jets were open? 3 What were the dimensions of the room? 4 How far was the body found from the open gas jets? 5 Was there an opportunity for a draft through the room? 6 What were the meteorological conditions on the day of death?

From the facts submitted it would be impossible to express an opinion whether the assault was perpetrated after the inhalation of gas. In any circumstances this would be a difficult matter. However, it is difficult to conceive that an assailant would bind a woman's hands and feet, turn on the gas and return later for the assault. If the gas permeated the room in sufficient concentration to kill the victim, the assailant would certainly become asphyxiated if he remained.

While illuminant gas is slightly lighter than air, it could accumulate and has accumulated in rooms with windows and doors open in sufficient quantities to kill an inmate.

MASSIVE EDEMA OF FEET AND ANKLES OF
UNDETERMINED CAUSE

To the Editor—A white woman aged 42 has a massive edema of the feet and ankles. The cardiac blood and urinary findings are negative. The edema is periodic and the swelling is usually occasioned by hot weather. Sometimes the swelling subsides almost entirely during the night but when she arises and after pursuing her daily routine for several hours the feet and ankles again swell to enormous proportions. There is no redness and little or no pain but great discomfort and embarrassment. Could this be an incipient erythromelalgia? These conditions have obtained for several years. Would you please suggest a proper regimen? Any other information will be appreciated. James A Laird MD Chicago

ANSWER—As a general proposition the initial symptom of erythromelalgia is pain. The pain is succeeded by redness and swelling, but the swelling does not usually assume massive proportions. The fact that there is no disease of the circulation or kidney would point toward a local cause. Swelling of the extremities in hot weather is not uncommon in those who have congenitally deficient veins and in varicose veins. Such swelling does not assume massive proportions, however unless the varicose veins are quite evident. One should next consider obstruction to the venous or lymphatic flow. Tumors of the pelvis and old thrombophlebitis of the pelvic veins are leading causes of such obstruction. An old lymphadenitis is a possible but not probable cause. Parasitic infestation of the lymph spaces must be considered.

Until the cause can be discovered, a definite plan of treatment is difficult to prescribe. In general the weight should be reduced if there is any tendency to overweight. The feet should be kept elevated at every opportunity and some sort of additional support should be given to the circulation. An elastic or mesh stocking should be applied while the swelling is absent. This support should extend from the tips of the toes to well above the knee. While this will not remove the cause of the swelling, it will certainly improve the esthetic effect and remove some of the embarrassment.

STERILIZATION OF BITCHES BY X RAYS

To the Editor—Is it practicable to sterilize female dogs by means of high voltage roentgen therapy? I realize that ovulation is brought about by mating while heat is the result of endocrine stimulation. If it is possible to inactivate the ovaries will the animal still have estrus?

M D Pennsylvania

ANSWER—Veterinarians do not consider it practical to sterilize female dogs by means of high voltage roentgen therapy. In a few cases bitches have been sterilized by this method and estrus was inhibited. When all ovarian tissue is removed surgically, as this is usually done in veterinary practice estrus always ceases.

FLOATING OPACITIES IN HIGH MYOPIA

To the Editor—I should like to have the most recent information on the formation and treatment (prevention) of floating opacities in high myopia

Jacob Aisenstat, MD New York

ANSWER—There is really no effective treatment for the floating opacities which occur in high myopia. They are due to disorganization of the vitreous, apparently as a result of the increased size of the vitreous cavity, which necessitates the passage of increased amounts of fluid into the vitreous gel. Such opacities in themselves do not affect vision and merely result in slight annoyance to certain persons. Such persons can only be reassured as to their harmless character. Opacities actually due to myopia must be distinguished from those occurring in chorioretinitis of infectious origin and from those which occur at the onset of retinal detachment. Careful fundus study should distinguish these conditions each of which does require treatment. The atrophic fundus changes of high myopia must not be confused with those of chorioretinitis. While it is true that retinal detachment occurs more frequently in myopic eyes and that changes in the vitreous play a part in its development, it would seem wrong to alarm every patient who develops vitreous opacities by mentioning the danger of detachment. Persons with high myopia may well be cautioned against violent exertion involving severe muscular strain or the danger of blows to the head but use of the eyes in reading does not involve a danger of retinal detachment.

INTERMITTENT HYDRARTHROSIS

To the Editor—A woman aged 35 has had an intermittent hydrarthrosis of the right knee for the last five years. Without fever or other systemic symptoms the knee joint fills with fluid within twenty-four hours and the condition subsides spontaneously after two or three days. There is no history of an injury to the knee although the patient says that since her high school days the knee would occasionally give out momentarily without swelling or pain. The hydrarthrosis first appeared about a year after the patient's first pregnancy; it disappeared during her second pregnancy and recurred about six months after the birth of her second child. The swelling now appears twice each month—about midway between the menstrual periods and within twenty-four hours of the onset of each period. Her health is otherwise good. She has a mild vasomotor rhinitis and a familial allergic background. Her blood shows a 3 per cent eosinophilia. The erythrocyte sedimentation rate is normal. In the last five years she has been subjected to removal of a devitalized tooth, vaccine therapy, a course of progesterone therapy, histaminase and histamine desensitization, all without effect on the hydrarthrosis. Any suggestions would be welcome. Herman J. Smith, MD, Des Moines, Iowa.

ANSWER—Most cases of intermittent hydrarthrosis of the type described usually represent an atypical form of rheumatoid arthritis. The very fact that the patient experienced complete remissions during her first and second pregnancies argues strongly in favor of this diagnosis.

Aspiration and detailed chemical analysis of the synovial fluid might prove to be of considerable diagnostic help.

The 3 per cent eosinophilia is not unusual for a person with rheumatoid arthritis.

As to treatment the following should be considered: rest, a high caloric, high vitamin diet, an ace bandage at the time of the effusion and any other supportive measures which seem indicated. High voltage roentgen therapy and synovectomy have at times been thought to be helpful in cases of this type.

DENTAL EXTRACTION AND EMBOLISM

To the Editor—Will you please be kind enough to answer a question for me? I am a dentist and I wonder if you know of any data which might substantiate the claim that a patient had died from embolism following the extraction of teeth. Any information which you may supply on the subject of emboli and their relation to the extraction of a tooth or teeth will be most appreciated. Walter E. Brehm, DDS, Lagan, Ohio.

ANSWER—Careful search of the medical literature has disclosed no reported instance of massive embolism of the lungs following the extraction of teeth. This is parallel with the experience of several oral pathologists and clinicians who have not heard of such an occurrence. On the other hand, minute emboli following tooth extractions are probably of frequent occurrence but produce no noteworthy clinical symptoms. But if these emboli carry bacteria, and especially pathogenic bacteria, they may cause septic processes in the lungs or elsewhere. Deaths have been reported in the form of septicemia or pyemia and as following such a train of events. Recently there have been a few reports of positive blood cultures immediately after tooth extractions, particularly of teeth that are quite loose or surrounded by deep pyorrhea pockets.

SUPPURATIVE LYMPHADENITIS FROM TULAREMIA

To the Editor—What can be done for a girl 4 years of age who has a constant draining node in the left axilla? The cause is tularemia. This disease was contracted eight months ago. The first lesion occurred on the left hand and the base of the index finger. She was rather sick for a month and seemed to respond to sulfathiazole medication. Since the onset she has had several bouts of fever and at that time the axillary gland would swell and drain. Any information would be greatly appreciated. Thomas DeChairo, MD, Westmoreland, Pa.

ANSWER—At this stage secondary infection with skin cocci probably contributes considerably to the chronicity of the suppurative lymphadenitis. Establishment of adequate dependent drainage, with wet dressings of magnesium sulfate solution, and twice daily irrigations of the wound with an aqueous solution of 1:1,000 each of methylrosaniline and acriflavine base should suffice to insure healing.

BLOOD PRESSURE AT HIGH ALTITUDES

To the Editor—Kindly describe the effect on the otherwise normal blood pressure of an altitude of 30,000 feet. MD, New York.

ANSWER—At an altitude of 30,000 feet it is impossible to maintain sufficient oxygen tension in the tissues to support life unless supplementary oxygen is supplied by adequate oxygen equipment. For this specific circumstance (barometric pressure 225) an inspired mixture the minimum content of which must be over 80 per cent oxygen would be necessary. If the oxygen tension in the tissues is maintained at a normal level there should be little appreciable change in blood pressure at that altitude.

REACTION TO SULFATHIAZOLE IN COLITIS

To the Editor—A young man has a case of chronic ulcerative colitis which has completely failed to respond to the regular treatment including sulfaguanidine by mouth. I am wondering if a solution of sulfathiazole has ever been used locally to the lower colon in the form of an enema in this condition and if it would have any ill effects other than the regular reactions which may be expected from this drug.

R. S. Lander, MD, Victoria, Texas.

ANSWER—Ill effects would probably not be produced by a solution of sulfathiazole other than the regular reactions which may be expected from the use of this drug. The solubility of sulfathiazole in water is only about 0.06 per cent, but it would be advisable to make suitable determinations from time to time to ascertain whether undesirable effects are being produced.

TOTAL ALOPECIA

To the Editor—In The Journal June 27, 1942, page 760, M. O. Arizona inquires about the endocrine aspects of a case of alopecia areata which became total despite treatment with thyroid and anterior pituitary but improved for a short time during pregnancy and lactation. The endocrine dysfunction may possibly be secondary to a focus of infection or to autonomic imbalance as the following case is illustrative. A white woman aged 34, married with two children, seen Jan. 9, 1939, complained of frontal headaches, occasional dizziness and loss of hair of the head and eyebrows for ten months. During that time she had been under the care of a dermatologist, a gynecologist and an endocrinologist without result. She wore a wig. Examination revealed total baldness, lack of eyebrows and lashes except for a few hairs remaining in the right lower lid and sparse axillary and pubic hair. The Wassermann reaction was negative. The urine normal. The hemoglobin 90, pulse rate 84, blood pressure 112 systolic and 74 diastolic, weight 109 pounds (49 Kg.), menses regular and the bowels regular. Examination of the heart, lungs, abdomen and pelvis was negative. Roentgenograms of the teeth, sinuses and sella turcica showed nothing pathologic. Vision is 20/20—1. The media and fundi are normal. The visual fields for white and colors are normal. The total refractive error under a mydriatic is +0.50 D sph +0.50 D cyl axis 90. Prescription was +0.50 D cyl axis 90, both eyes for headaches. Examination of the ears, nose, throat and larynx was negative except for small buried tonsils from which pus could be obtained on suction. January 16, 1939, there was a thick postnasal drip from the ethmoid sinuses. The dermatologist sees many cases of alopecia areata and totalis in the course of practice. If more of these patients were thoroughly worked up and treated possibly the results would be better. Another case of alopecia areata of the scalp and beard in a physician was alluded to by attention to the gastrointestinal tract. This patient was allergic to a few foods and had a low grade ileocolitis. Removal of the offending allergens and alcohol, a low protein diet and injections of an autogenous streptococcus vaccine produced a cure after dermatologic treatment had accomplished nothing. When the hair returns it is usually absolutely white and gradually becomes pigmented. The process requires about a year if the patches are fairly large. Sidney P. Levey, MD, New York.

THE INDICATIONS AND PROGNOSIS IN UNILATERAL NEPHRECTOMY

CHAIRMAN'S ADDRESS

VINCENT J. O'CONNOR, M.D.
CHICAGO

There is no procedure which should be approached with more careful deliberation on the part of the surgeon than the operation for removal of a kidney.

Aside from the occasional emergencies of traumatic rupture, unilateral massive hemorrhage or fulminating infection, the operation is a relatively elective one on the part of both patient and surgeon. Fortunately, modern diagnostic procedures, properly applied and evaluated, usually leave little doubt as to the cause of unilateral renal disease and in the indications for removing the affected kidney. Not infrequently lesions exist in both kidneys, and the less affected one can be satisfactorily restored to normal function by manipulative or surgical means prior to the removal of the one which is hopelessly destroyed.

The removal of a kidney can be satisfactorily accomplished by any surgeon with the necessary skill and technical experience, but the indications that prompt the procedure must be based on the results of an accurate and complete urologic investigation which not only surveys the condition of the entire urinary tract but also demonstrates that no surgical procedure short of nephrectomy is sufficient to rectify the condition.

In the last twenty years, largely through the specialized attention of urologists, great strides have been made toward conservative renal surgery. Partial resection of the kidney, plastic operations on the renal pelvis and the ureters, nephrolisis and ureterolysis combined with nephropexy and progressive dilation of ureteral strictures through the cystoscope have made nephrectomy a far less frequent operative procedure than in the previous decade. It is often a matter of fine judgment on the part of the surgeon at the time of operation as to whether the kidney should best be removed or less radical measures adopted in the hope that function and health may be restored. The necessity for secondary nephrectomy at a later date occasionally retards what had seemed good conservative policy at the first operation.

Nephrectomy is a more recent operation than many of the commonly practiced surgical procedures. Inadvertent nephrectomy was first successfully performed by Wolcott in America in 1861. Dr. Gustave Simon of Heidelberg is credited with the first deliberate

nephrectomy on Aug. 2, 1869. He had previously determined, as a result of animal experimentation, that removal of one kidney would not interfere with continued normal life provided the remaining kidney was in a healthy state. The indication for this operation was a left ureterovaginal fistula resulting from a previous hysterectomy in a woman aged 46. The patient was known to be alive and well two years later.

Immediately following the work of Simon the mortality associated with nephrectomy was so great as to cause its employment only infrequently. Following the development of aseptic surgery with the improvement in anesthesia and surgical technique the operative mortality has decreased until it is not greater than that associated with other major surgical procedures.

In 1902 Kuster collected the statistics of 1,521 nephrectomies performed by different surgeons giving a mortality for all cases of 34.36 per cent for the transperitoneal and 12.08 per cent for the extraperitoneal removal of the kidney.¹ Since that time the operation has become a common procedure and the mortality now reported by skilled urologists varies between 20 and 60 per cent.

Your chairman wishes to discuss as briefly as possible a personal experience in private practice during the past twenty-two years in which 219 nephrectomies have been performed. The personal relationship with these patients has permitted a relatively complete follow-up record.

As will be readily understood the underlying pathologic condition classified as hydronephrosis, pyonephrosis and lithiasis renders complete differentiation impossible.

There have been five operative deaths, a mortality of 2.28 per cent. A man aged 21 with a huge right caseous tuberculous kidney died forty-eight hours after operation with multiple pulmonary emboli. The renal pedicle could not be ligated without injury to the inferior vena cava. Had pedicle clamps been left in situ without ligation, the result might have been different. A man aged 68, greatly debilitated from renal hemorrhage and pain, died on the fifth day after the removal of a large hypernephroid carcinoma. One woman aged 56 died on the sixteenth postoperative day after removal of a right pyonephrotic kidney; clamps had been left on the pedicle for three days following an unsuccessful attempt at ligation. Sepsis was the cause of death. Another woman, aged 52, who had had two previous operations for right renal calculi, died on the fifth day after the subcapsular removal of a chronically pyonephrotic kidney. Shock and sepsis caused death. A man aged 72 died of coronary throm-

Read before the Section on Urology at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1942.

basis on the third postoperative day after removal of a right kidney filled with staghorn calculi. The patient had long postponed operation, which was finally imperative to relieve constant pain.

Gutierrez,² among others, has called attention to the desirability of performing carefully planned nephrectomy in two stages when the patient has advanced pyonephrosis and is too ill to be subjected to primary nephrectomy. Drainage of a pyonephrotic kidney to relieve the gravity of the symptoms before a radical operation is undertaken is occasionally a wise procedure, and it may be the means of saving the life of the patient.

It is to be noted that in this series nephrectomy was performed with almost equal frequency for tuberculosis, lithiasis and pyonephrosis.

RENAL TUBERCULOSIS

There were 42 nephrectomies for renal tuberculosis. One death, already mentioned, made an operative mortality rate of 2.38 per cent. Because of extensive ureteral involvement, complete removal of the ureter and kidney (primary nephroureterectomy) was per-

formed in 4 instances. Evidence of continued tuberculous activity prompted secondary ureterectomy in 2 cases. This proved to be a valuable procedure in this limited experience, as shown by rapid improvement in previously intractable tuberculous cystitis. In none of our patients was the ureter brought out to the skin. In most instances the stump after being doubly ligated was treated with phenol or the actual cautery and anchored by suture to the edge of the psoas muscle. Only two wounds broke down, and these were successfully closed after four months by debridement and secondary suture. Primary healing occurred in 28 patients, a draining sinus persisting for from two to fourteen months in 11 patients.

Twenty-six of the tuberculous patients were females and sixteen were males. The youngest was a boy of 8 years operated on on July 26, 1922 and now in perfect health. The oldest was a man aged 64, operated on on Oct. 30, 1928, who now reports doing some work on his farm and enjoying "fair" health at the age of 78. Thirty-six of these patients have complete follow-up data. Four, all women, died with urinary tuberculosis between three and five years after operation. A man operated on on Jan. 20, 1925 at the age of 30 died

in the Walter Reed Hospital in October 1938 from ascending urinary tuberculosis, which had been observed for thirteen years but could not be halted by any climatic or sanatorium treatment. It is possible that a cutaneous ureterostomy performed in time might have saved this patient's life. One woman operated on ten years ago is dying of carcinoma of the uterus but without evidence of urinary tuberculosis. Four patients died after seven, eight, ten and twelve years respectively from causes other than tuberculosis. Twenty-one patients are known to be alive and well without evidence of urinary tract tuberculosis after periods of from twenty-one years to one year after operation. Four patients are alive and active more than five years after nephrectomy but continue to suffer from tuberculosis of the bladder. Three of these have tubercle bacilli in the urine. Four of the sixteen men also had unilateral genital tuberculosis. Seven of these patients had had bone tuberculosis all apparently healed at the time of nephrectomy.

I believe with Colby,³ as frequently emphasized by Gilbert Thomas, that whenever possible all patients with renal tuberculosis should have the preoperative benefit of treatment similar to sanatorium care. In this way the general health may be greatly improved and an increased resistance to infection established. Unfortunately only 10 of these patients could be so treated. The same general principles apply after nephrectomy, including the judicious use of old tuberculin injections given intradermally. Eight of the younger patients have found new homes in the South west where general climatic conditions are more favorable for their continued good health.

LITHIASIS

Forty-one patients had the kidney removed because of stone formation. Nine of these had recurrent stone and had previously been subjected to pyelotomy or nephrotomy. I had formerly removed stones from the opposite kidney of 5 other patients. One patient, classified under lithiasis, had no stones in the pelvis, but the kidney having been removed for severe recurrent hemorrhage was found to have multiple collections of minute mucous acid calculi filling the renal tubules. This condition has been described by Lichtenstern⁴ as "microlithiasis." This patient has had no trouble in the remaining kidney during the past twelve years. Huggins⁵ has called attention to the frequency of microliths occurring in "stone forming" kidneys and it is possible that these may have been present in others of our group and escaped recognition by the pathologist. There was one death in this group, an operative mortality of 2.43 per cent. The youngest patient was a girl of 16 and the oldest a man of 82. Only 31 of these patients have complete follow-up records. Four are dead from causes not associated with the urinary tract after five, eight, nine and eleven years. Three patients died four, six and ten years after nephrectomy with infection in the remaining kidney. Twenty-four patients are alive and well, but 3 have calculi in the remaining kidney and 6 others have had recurrent attacks of pyelonephritis.

Postoperative measures have been directed toward the elimination of focal and renal infection, correction of dietary habits as determined by the chemical analysis of the stone, added vitamin ingestion and attention to proper urinary drainage of the remaining kidney. In recent years derivatives of mandelic acid and sulfanilamide have aided greatly in the elimination of infection in the remaining kidney. Parathyroid disease was not found in this series, although it has been observed in association with 3 patients with bilateral renal calculi none of whom were subjected to nephrectomy.

Control of urinary stone formation is still the goal of every urologist. This is a complex problem and notable progress has been made but much additional work remains to be done.

PYONEPHROSIS

Nephrectomy was performed on 40 patients with chronic massive infection of the kidney. The majority of these patients were in the fourth and fifth decades of life. There were two deaths in this group, an operative mortality of 5.0 per cent. Seven of these had been previously subjected to surgery for renal calculi. In my experience the removal of a chronically pyonephrotic kidney is often the most difficult nephrectomy. Dense adhesions to all the surrounding structures, difficulty in ligation of the renal pedicle and chronic sepsis in a debilitated patient make this operation a formidable one in the most experienced hands. Three of these patients were operated on in two stages. All recovered. Eight kidneys were removed by the subcapsular method. Two of the latter patients died. The youngest patient was a boy of 6 years now living and well at the age of 18. The oldest a man of 74 lived in comfort for five years when death occurred from pneumonia. Three of the older patients died after three, nine and eleven years respectively with infection of the remaining kidney. A girl of 18 developed a pyonephrosis in the right kidney five years after removal of the left one for pyonephrosis. A nephrostomy was done and the patient lived a miserable existence for three years, when she died in uremia. Twenty-six of these patients are known to be alive, 11 more than five years and 15 more than ten years. Modern urinary chemotherapy has been responsible for the elimination of infection in the remaining kidney of 10 patients during the past five years.

HYDRONEPHROSIS

While conservation of the kidney by pyeloplastic procedure is the method of choice in hydronephrosis,⁶ nephrectomy is indicated when renal destruction is so advanced that restoration of function is impossible. This condition resulted in thirty of the nephrectomies in this series. The majority of these patients were in the second and third decades of life. Successful conservative procedures were carried out on 7 patients on the opposite life sustaining kidney before the functionless one was removed. There was no death in this group. Twenty-seven of these patients have been accurately observed since operation. Only 1 is known to be dead, as a result of a motor accident.

The bilateral tendency of congenital hydronephrosis makes it imperative that the remaining kidney be carefully studied at suitable intervals. Excretion urography has proved to be an informative follow-up procedure.

TUMORS OF THE ADULT KIDNEY

In this series of 29 patients operated on for renal cortical tumors in which there was one operative death only a few interesting facts were developed by careful follow-up study. Sixteen were males and 13 were females. The youngest patient was 37 years old, she is living and well more than three years after operation.

Six patients died within the first twelve months. Ten patients died between two and one-half and three years after operation. Autopsy in one of these, a man aged 63 at death, showed no evidence of tumor, death having been due to pneumonia. One patient operated on in 1932, and in apparently good health for nine years, is dying with what appears to be metastatic hypernephroid carcinoma of the brain.

Nine patients are living and apparently well. A woman aged 50 at the time of operation on Aug. 27, 1933 is apparently in good health. Two patients are well after eight and seven years respectively. Six patients are living and without apparent recurrence for more than four years but less than six years. Three of these 29 patients can hardly be considered in a survival rate study, other than operative since only eight, eleven and fourteen months respectively, have elapsed since operation.

TUMORS OF THE RENAL PELVIS

In this series there have been 10 patients with tumors primarily arising from the renal pelvis. Eight of these were papillary carcinomas and two were of the squamous cell variety. The youngest patient in this group a man aged 29, had a papillary growth in the bladder and a large papillary carcinoma of the renal pelvis. He is well nine years after complete nephroureterectomy and suprapubic coagulation of the bladder implant. One patient lived seven years after nephrectomy and then died of pneumonia. Autopsy showed no recurrence. Another patient lived eleven years after nephrectomy and died at the age of 80 years with carcinoma of the rectum. A woman, in whom all of the ureter except the intravesical portion was removed with the kidney for papillary carcinoma, died four years and two months later with massive recurrence in the ureter and bladder. Another patient with multiple bladder implants died of urosepsis three years and five months after complete nephroureterectomy. Three patients are living and apparently well six, five and four years respectively, after complete nephroureterectomy for papillary carcinoma of the renal pelvis. Both patients with squamous cell carcinoma died within one year after nephrectomy.

As will be noted from this small experience, the prognosis in papillary carcinoma of the renal pelvis has been relatively favorable. This has been due in large part to the recognition of the necessity for doing complete nephroureterectomy (including the intramural portion of the ureter) in every instance in which this type of tumor is recognized.

PRIMARY TUMOR OF THE URETER

There were 4 patients all males, in whom complete nephroureterectomy was done for primary tumor of the ureter. These patients are all living and apparently well, five years, three years, two years and fourteen months, respectively. In each the growth was diagnosed as papillary carcinoma and there was no invasion of the renal pelvis or bladder.

Three of these 29 patients can hardly be considered in a survival rate study, other than operative since only eight, eleven and fourteen months respectively, have elapsed since operation.

TUMORS OF THE RENAL PELVIS

In this series there have been 10 patients with tumors primarily arising from the renal pelvis. Eight of these were papillary carcinomas and two were of the squamous cell variety. The youngest patient in this group a man aged 29, had a papillary growth in the bladder and a large papillary carcinoma of the renal pelvis. He is well nine years after complete nephroureterectomy and suprapubic coagulation of the bladder implant. One patient lived seven years after nephrectomy and then died of pneumonia. Autopsy showed no recurrence. Another patient lived eleven years after nephrectomy and died at the age of 80 years with carcinoma of the rectum. A woman, in whom all of the ureter except the intravesical portion was removed with the kidney for papillary carcinoma, died four years and two months later with massive recurrence in the ureter and bladder. Another patient with multiple bladder implants died of urosepsis three years and five months after complete nephroureterectomy. Three patients are living and apparently well six, five and four years respectively, after complete nephroureterectomy for papillary carcinoma of the renal pelvis. Both patients with squamous cell carcinoma died within one year after nephrectomy.

As will be noted from this small experience, the prognosis in papillary carcinoma of the renal pelvis has been relatively favorable. This has been due in large part to the recognition of the necessity for doing complete nephroureterectomy (including the intramural portion of the ureter) in every instance in which this type of tumor is recognized.

PRIMARY TUMOR OF THE URETER

There were 4 patients, all males, in whom complete nephroureterectomy was done for primary tumor of the ureter. These patients are all living and apparently well, five years, three years, two years and fourteen months, respectively. In each the growth was diagnosed as papillary carcinoma and there was no invasion of the renal pelvis or bladder.

TRAUMA

Under the heading of trauma I include 2 patients whose kidney was removed because of massive hemorrhage after accidental rupture by violence, one by perforation from gunshot and three for persistent uterovaginal fistulas from surgical accidents during hysterectomy. During this time the diagnosis of ruptured kidney has been made in our service on 48 persons, and since only 2 required nephrectomy as an emergency measure, I feel that conservative treatment in these cases should be given full consideration before operative intervention is undertaken.

ATROPHIC PYELONEPHRITIS

Atrophic pyelonephritis is given a distinct classification in this series because this condition represents a slow progressively destructive lesion of the kidney, occurring in my experience in younger persons. Six of these patients have survived for from periods of ten to five years after nephrectomy.

CARBUNCLE OF THE KIDNEY

Four patients had the kidney removed because of massive carbuncular disorder. In none of these instances did it seem wise to attempt excision of the carbuncle or incision and drainage. These patients were 17, 19, 21 and 40 years of age respectively. All recovered and are living and well over periods of twelve, eleven, six and five years. While it is always advisable to attempt less radical measures than nephrectomy in carbuncle of the kidney, massive involvement may make nephrectomy imperative.

ECTOPIA OF THE KIDNEY

Ectopia of the kidney has been classified separately as an indication for nephrectomy. In this series 2 males and 3 females suffered from unilateral renal ectopia of the kidney. In the men hydronephrosis and pyelonephritis with multiple calculi constituted the primary pathologic conditions. In the women pain and recurrent pyelonephritis prompted nephrectomy. In 2 of the women dystocia had occurred because the misplaced kidney interfered with the passage of the fetal head. Renal pain and recurrent infection resulted and the previously symptomless kidney developed indications for nephrectomy. All these patients are living and well from three to eleven years after operation.

Nephrectomy for unilateral renal ectopia is somewhat more difficult than the usual lumbar operation. The kidney which is molded in the hollow of the sacrum has a multiple and varied blood supply. It might be emphasized that if a urologic examination made before or during pregnancy, reveals renal ectopia, a definite indication exists for abdominal cesarean section. Two patients, so delivered, have had no trouble in the nontraumatized ectopic kidney during the past five years.

SOLITARY CYST OF THE KIDNEY

Solitary cyst of the kidney is rarely an indication for nephrectomy. These benign cysts can usually be resected or destroyed without interference to continued renal function. The cysts of 2 patients, however, occupied the central portion of the kidney and had caused such advanced renal destruction that it was advisable to remove the kidney. Both patients recovered and are living and well five and nine years respectively after operation.

HORSESHOE KIDNEY

In 7 patients of this series one half of a fused kidney was removed after division of the isthmus. Two were hydronephrotic, 1 was tuberculous, 3 were pyonephrotic and 1 contained multiple recurrent calculi. All these patients recovered and have normal function in the remaining renal tissue. All were operated on through the extraperitoneal lumbar approach.

NEPHRECTOMY AND HYPERTENSION

Goldblatt and others have shown that the production of renal ischemia by constriction of the renal artery is followed by hypertension in animals. When the kidney so affected is removed, the blood pressure returns to normal. An increasing record of clinical observations by many urologists has shown that hypertension may result from pathologic conditions of the kidney. When this disease is unilateral and the opposite kidney is functionally normal and unaffected, nephrectomy may be followed by a reduction in the blood pressure level in a varying percentage of individuals.

In our series there were 9 patients in whom nephrectomy was followed by an apparently permanent improvement in their hypertensive condition. The indication for nephrectomy in these patients was calculus disease 3 patients, hydronephrosis 3, congenital hypoplasia 2 and primary tumor of the ureter with hydronephrosis 1.

A larger number of patients were observed who had a temporary relief of hypertension for periods of a few months to one year. In these the blood pressure gradually returned to the preoperative level. In the 9 patients cited the relief of hypertension has continued for from three to nine years and is therefore regarded as having been directly due to the nephrectomy.

COMMENT

As Deming⁷ has recently stated it is not enough to compile and discuss mortality figures of a series of nephrectomies. It is important for us to learn from our own experience, coupled with that of others, what factors will give us a lower operative mortality and an improved long range prognosis for the patient. Nor should our responsibility to the patient terminate with his successful convalescence from the operative procedure. We must firmly convince the patient that intelligent cooperation with his physician will often enable him to avert the development of lesions in his remaining kidney.

There are a number of factors, aside from the age at operation, which influence the length of life after unilateral nephrectomy. Some of these factors depend on the patient's attitude toward his future mode of life while others depend on the physician's recognition of the problems which may arise. The prevention of recurrent calculus formation, the elimination of systemic and urinary tract foci of infection and the maintenance of adequate urinary drainage are prime necessities after nephrectomy.

Aside from the danger of recurrence in malignant disease and in advanced urinary tuberculosis, such a program, intelligently enforced, should lead to a normal expectancy of life in most instances.

ODOR IN THE ORR TREATMENT OF OSTEOMYELITIS AND ITS PREVENTION BY LACTOSE

ALLAN D WALLIS, MD
AND
MARGARET J DILWORTH BS
PHILADELPHIA

One of the few aspects of the Orr treatment of osteomyelitis about which there is universal agreement is the unpleasantness of the odor which is apt to develop in the casts. Remarkably little attention seems to have been paid to the cause and prevention of this odor. It is our purpose herein to offer a hypothesis as to the cause and to suggest a simple method for the prevention.

REVIEW OF THE LITERATURE

Orr¹ states that bad odor is always due to a complicating mixed infection. Finckel² notes that the odor is worse when the wound is inadequately drained. Aside from this we have been able to find no speculation as to the cause.

Various remedies have been suggested. Orr¹ noted some decrease in the odor when using iodoform gauze soaked in balsam of Peru. McAleese³ used oil of cloves paste instead of petrolatum gauze. Attempts to replace one odor with another are frequently made externally by sprinkling such substances as oil of cloves or oil of wintergreen on the surface of the cast. We have made a trial of sealing the pores of the cast by painting it with varnish or with celluloid dissolved in acetone. This served only to delay the appearance of the odor. Baer⁴ stated that maggots stopped the odor during the first application. Trueta⁵ recommended the application of brewers yeast to the wound at the time of changing of the cast for the purpose of decreasing the odor. He said 'a certain smell did remain but it was less disagreeable'. We have used this method in 2 cases without strongly affecting the odor. One patient had a transient urticarial reaction of moderate severity.

USE OF DEODORANTS IN THE DRESSINGS

We have tried impregnating the dressings with various deodorants. Of these the most effective was zinc sulfocarbolate. Gauze dressings soaked in a 2 per cent solution of this and dried before use definitely diminished the odor, but the results left much to be desired. Reference to the use of mercury bichloride in the plaster water will be made.

CAUSE OF THE ODOR

It seems obvious to the most casual observer that the well developed odor resembles nothing else so much as that due to the putrefaction of a decaying animal body and this is the assumption on which we have proceeded. Rettger⁷ points out that the term putrefaction has acquired two distinct meanings. In the more general usage it signifies decomposition of protein material through bacterial action as against fermentation or decomposition of carbohydrates. He prefers it "in the more restricted sense to mean anaerobic decomposition of protein with the production of foul smelling products which are characteristic of cadaveric decomposition." Protein breakdown in the wider sense is better referred to as proteolysis.

Writers on the subject of putrefaction stress the importance of the part played by anaerobic bacteria in the process. In discussing the cause of the putrid odor in peritonitis following appendicitis Altemeier⁸ came to the conclusion that putrid pus always indicates the presence of anaerobic organisms. In the case of resistant radionecrotic ulcers following malignant tumors Freeman¹⁰ recovered anaerobic organisms from thirty-five lesions having a foul odor and noted that as the lesions became odorless under treatment with zinc peroxide the anaerobes disappeared, as shown by cultures taken returning as the odor recurred on cessation of treatment. The demonstration of anaerobes by Trueta⁵ in osteomyelitis wounds during healing furnishes an important link in the chain of evidence.

Contaminating organisms presumably gain access to osteomyelitis wounds by direct implantation at the time of operation or redressing. It is increasingly recognized that sepsis in the operating room is only relative. Cultures of clean wounds show contaminants in a high percentage.¹¹ Primary union of such wounds is a tribute to the resistance of the host. In osteomyelitis wounds a micro-organism on arrival would find an environment more favorable to survival than in wounds of more ordinary type. Warmth moisture suitable pH and nutrient substances are present particularly the products of autolysis to be mentioned later. The field is probably deficient in the cellular and humoral factors of immunologic resistance which protect normal tissues. The pre-existing etiologic aerobes that have inevitably escaped the surgeon are creating an atmosphere favorable to anaerobes by exhausting the available oxygen. The pathogenic aerobes prepare the soil in another way also. As Weinberg¹² and Ginsbourg¹ point out highly proteolytic organisms are rarely pathogenic. They usually need the assistance of the more toxic less proteolytic organisms in order to become established. However since similar conditions prevail in ordinary soft tissue wounds the probability arises that some unknown factor peculiar to bone is present. In any case the fact that the wound is

covered and more or less sealed doubtless favors anaerobiosis. Similar odors may develop in covered soft tissue wounds if an element of pressure is added.

While it is theoretically possible for contaminants to reach the wound by way of the blood stream the observations of Ori-Ewing, Scott and Gardner¹³ indicate that this does not ordinarily occur. Through a small window incorporated in the cast they took cultures of material from compound fractures during treatment by the closed method and found that new organisms appeared only after changes of the cast.

Redressings under the closed cast method in cases of osteomyelitis are often performed without the operating room asepsis which Ori advocates. This may explain why odor is more likely to develop in subsequent casts than in the original.

ROLE OF AUTOLYSIS

The question arises as to the part played by autolysis in the proteolytic process under consideration. It seems likely that at least a narrow zone of tissue bordering the wound undergoes ischemic death immediately following an Ori debridement. The use of tincture of iodine and alcohol in the authentic Ori technique probably favors such necrosis. There is evidence which indicates that the protein breakdown products of the self digestion of this tissue are contributory if not essential to the proteolytic action of the anaerobic organisms. Sperry and Rettger¹⁴ have shown that in the absence of cleavage producing substances like proteolytic enzymes (or strong acid or alkali) bacteria cannot initiate the decomposition of native or unchanged protein by direct action. Thus even the most actively proteolytic organisms may starve to death on egg albumin or serum albumin if there is not access to simpler nitrogenous substances from which to start the production of enzymes.¹⁵ This may explain why devitalized muscle is necessary for the development of gas gangrene. Weinberg and Ginsbourg¹ call attention to the fact that inflammatory exudates contain protein breakdown products which are more readily attacked by many organisms than is native protein but in a well debrided wound the autolytic process would probably be the first to become effective.

The importance of autolysis in putrefaction *in vitro* is indicated by the fact that whereas inoculation of sterile muscle (obtained from a clean operation) with organisms from a foul osteomyelitis wound results in a characteristic putrid odor, putrefaction does not occur if the muscle has been autoclaved before inoculation, the autoclaving presumably destroying the autolytic enzymes.

On the other hand it may be shown that autolysis alone does not result in putrefaction. We have incubated at 37 C. fragments of sterile muscle in test tubes which were rubber stoppered to preserve moisture. These were examined periodically up to thirty weeks and as long as they remain sterile no odor could be

detected. Autolytic proteolysis proceeds only to the amino acid stage. Decarboxylation and deamination (with the production of foul odors) occur only when the amino acids are further split.

NATURE OF THE ODORIFEROUS SUBSTANCES

Rettger and Newell¹⁶ state that among the foul products of putrefaction mercaptans are important, indole, skatole and hydrogen sulfide are less important. According to Bodansky,¹⁷ mercaptans may be formed by bacterial action on the amino acid cystine which is present in higher percentage in bone than in muscle. Other foul products that may be formed are putrescine and cadaverine derived respectively from the amino acids arginine and lysine.

The importance of mercaptans in the clinical odor under consideration is indicated by the fact that foul dressings from these wounds are immediately deodorized by immersion in a solution of mercury bichloride. The term mercaptan means 'having an affinity for mercury' with which mercaptans react to form stable odorless compounds.¹⁸ Clinical application of this principle was tried by adding mercury bichloride to the water in which plaster bandages were soaked making a concentration of 1:1000. This method was used in a few cases and definitely diminished but did not entirely eliminate the odor, probably for lack of intimate contact.

PROTEIN SAVING EFFECT OF CARBOHYDRATES

Proceeding on the assumption that the foul odor of osteomyelitis is of proteolytic origin, it seemed logical by implanting a sugar in the wound to take advantage of the well established principle that utilizable carbohydrate retards bacterial proteolysis. As Kendall, Day and Walker¹⁹ express it "fermentation takes precedence over putrefaction", that is to say, those bacteria which can utilize both carbohydrate and protein attack the former in preference to the latter when the two are simultaneously available. When bacteria utilize protein merely for their structural needs, the nitrogenous products of proteolytic activity are not formed as they are when protein is utilized for fuel.²⁰ Availability of carbohydrate for fuel in this way spares protein and foul products are not formed. The absence of putrefaction in raw milk is a commonplace illustration. This is also the principle on which have been based attempts to relieve so-called autointoxication by feeding lactose and *Bacillus acidophilus*. In fact it was this method that first suggested to us the present application of lactose to osteomyelitis.

Dextrose reaching an osteomyelitis wound from the circulation would be inadequate in amount for this purpose since its maximum concentration would be about 0.2 per cent, and furthermore it would be destroyed by the leukocytes of the exudate.

Such benefit as has been obtained by the implantation of fresh brewers' yeast in these wounds may be due to sugars present in the yeast mixture.

The mechanism whereby protein is spared by utilizable carbohydrate will be made the subject of a separate report.

CHOICE OF SUGAR AND CONCENTRATION

In the selection of a sugar for clinical use, the choice seemed to lie between dextrose and lactose. Both are normally present in the body, fermentable by a wide variety of organisms, readily available commercially, cheap and harmless. Lactose was chosen instead of dextrose because of the probability that the latter would be destroyed by the leukocytes in the wound.²¹ Lactose is not subject to such destruction. Lactose is also preferable for physical reasons, since its molecule is larger than that of dextrose; a solution of it isotonic with the blood contains more sugar, and loss by absorption from the wound should be less. If lactose were absorbed from a granulating surface, it presumably would be excreted in the urine as in the lactosuria of lactation. In 2 of our cases in which tests were made forty-eight hour specimens of urine following implantation contained no lactose.

In determining the concentration of lactose to be used osmotic pressure was taken into consideration. Theoretically, a 10.8 per cent solution of lactose is isotonic with 0.85 per cent sodium chloride. Actually it was found *in vitro* that not until the lactose solution was made as weak as 2 per cent did well defined hemolysis occur, and in the other direction crenation of red cells was negligible at 18 per cent (saturation).²² To insure an adequate amount of sugar for a period of weeks, relatively high concentrations seemed desirable. Accordingly for practical use a strength of approximately 18 per cent was chosen. For periods longer than we have used to date it is possible that higher concentrations may be needed. These could be provided by adding crystalline lactose to the dressings.

CLINICAL USE

U. S. P. lactose is dissolved, with the aid of slight heating, in distilled water to make an approximately 18 per cent solution. This is autoclaved in Erlenmeyer flasks, each containing about 50 cc. The flasks are capped with parafilm and stored until needed. Flasks showing visible growth of mold should, of course, be discarded. When a wound is to be dressed the contents of a flask are emptied into a sterile cup and the wound is filled with gauze dressings that have been dipped into the solution. About 50 cc. suffices for a wound of moderate size. Petrolatum gauze is not used. This pack is covered with a few dry dressings and the cast applied in the usual manner. The lactose is not allowed to come in contact with the plaster lest crumbling occur.

There would seem to be no risk involved in implanting this material, particularly in a granulating wound. White²³ has shown that granulation tissue is an excellent barrier to harmful substances. In his experimental animals large amounts of tetanus toxin were placed in wounds without ill effect provided the wounds were at

least five days old. He refers to similar protection demonstrated by Billroth (1865) who implanted putrid pus and by Afanassieff (1896) using anthrax bacilli. The development of a granulation tissue barrier may explain the postoperative disappearance of tetanus under the Orr technic. The same barrier would probably prevent contaminating bacteria from entering the wound out of the blood stream.

For use in a fresh wound at the time of operation the solution should be made with freshly distilled water as an added precaution against contamination with spores. That is, the solution should be made and autoclaved before the distilled water is more than 2 hours old. Although we have not tried it tap water could probably be substituted for distilled water in preparing solutions for use in old wounds provided fractional autoclaving is carried out.

RESULTS

Laboratory demonstration of the effectiveness of this method is easily made. A piece of raw butcher's meat is placed in each of two test tubes and inoculated with exudate or organisms from a foul osteomyelitis wound. To one tube is added a sugar free broth or other liquid and to the other a lactose solution. Within two to five days a putrid odor develops in the sugar free tube, growing progressively stronger, whereas in the lactose tube it fails to become established. Furthermore, visible disintegration of the meat proceeds much more slowly in the latter. *In vitro* a cheesy odor is apt to develop in the lactose tube but this is not evident *in vivo*, perhaps because of systemic absorption of lactic acid.

The clinical effectiveness corresponds to that in the test tube. Thus far we have used the method in 6 cases, 1 of which failed to respond. In the other 5 casts were maintained for periods up to six weeks without the development of a putrid odor. After seven weeks a slight odor, partly ammoniacal, partly foul, was detected in the immediate proximity of the cast. In these 5 cases the method was instituted at the time that the cast was changed, the condition of all of them being already definitely foul. In the sixth and unsuccessful case the method was instituted at the time of sequestrectomy. At that time the patient had had a foul sinus for more than two years. The failure is attributed to the presence of a putrefactive organism incapable of utilizing lactose. Exudate from this wound caused putrefaction of meat in a test tube despite the addition of lactose.

In 1 case a convincing control was established as follows: the putrid odor having been abolished by lactose, the latter was purposely omitted from a subsequent cast, whereupon the odor definitely returned and was again abolished by the addition of lactose to the next cast. In this case a foul sinus had been present for twenty-five years previous to operation.

In the course of our clinical use of lactose unexpected additional benefits became evident. Both the amount of exudate and the tendency to excoriation of the surrounding skin seem to be diminished. This is probably related to the fact that the production of proteolytic enzymes is inhibited, in the case of most organisms, by the presence of utilizable carbohydrate.²⁴

indicating that the biologic habits of the organism have been changed

No ill effects have been noted. The gauze is easily removed from the wound, which is not always the case when petrolatum gauze has been used. The usual healing process is not impaired.

COMMENT

That lactose in solution is not itself a deodorant can be demonstrated by placing a piece of foul dressing in it.

Discussion of the specific bacterial flora of these wounds has been omitted as it has with a few exceptions no direct bearing on the principle involved. Several observers have shown that a wide variety of bacteria is present up to the time of healing.²⁶ There are not many organisms that cannot attack sugar. *Bacillus pyocyaneus* is one of these and the lactose method does not abolish its odor which however is nonputrid and not particularly penetrating or objectionable. Among the putrefactive anaerobes *Clostridium histolyticum* is an exception in being unable to ferment carbohydrate and one would not expect a wound contaminated with this organism to respond to lactose.

We cannot agree with suggestions that a putrid odor occurring in a case of osteomyelitis is necessary or even beneficial. Trueta²⁷ states that the odor is not without some clinical significance. Donaldson and Joyce²⁸ noted that war wounds under the Wright hypertonic salt pack treatment were apt to do poorly when odor was lacking. They implanted the Reading bacillus (*Clostridium sporogenes*) in such wounds with development of a foul odor and clinical improvement which they attributed to proteolysis and possibly detoxification but it seems significant that before implanting the organisms they did a thorough debridement.

Lactose should prove a valuable addition to the Trueta closed cast method of treating compound fractures.²⁸

This principle should be applicable to the deodorization of putrid ulcerating malignant tumors or of ischemic gangrene from diabetes or other cause. In foul paranasal sinus infections or pulmonary abscesses crystalline lactose might be applied by insufflation.

It is a basic principle of the Orr method that frequency of changes of a cast has a definite influence on the rate of healing, the less often the cast is changed the more rapid will be the recovery. The use of lactose prolongs the interval between changes of the cast by diminishing the odor, the exudate and the cutaneous irritation which are probably the three most common reasons for changing the cast.

If the use of the sulfonamides fulfils its early promise of making possible primary closure of osteomyelitis and compound fracture wounds the Orr method will have only occasional application. In that case the greatest usefulness of lactose may well be found in nonorthopedic lesions.

Whether lactose should be implanted at the time of debridement as well as when the cast is changed is a question that remains to be decided. Perhaps the answer will depend on the circumstances of the individual case.

SUMMARY

The foul odor in osteomyelitis wounds treated by the Orr method is attributed to putrefaction by anaerobic bacteria incidentally implanted in the wound. Autolysis of devitalized tissue probably helps to initiate the proteolysis. Through the protein sparing effect of carbohydrates putrefaction may be retarded by implantation of utilizable sugar in the wound. For these reasons it is proposed that sterile 18 per cent aqueous lactose be added to the dressings at the time that the cast is changed.

CONCLUSIONS

1. The addition of lactose into osteomyelitis wound under the closed cast method has abolished the putrid odor in 5 of 6 cases. The usual healing process is not impaired.

2. The use of lactose seems to diminish the amount of exudate and the tendency to cutaneous irritation.

3. The use of lactose is suggested for deodorization of putrid lesions of nonosseous origin.

William A. Wolff, Ph.D., biochemist to the Pennsylvania Hospital, Philadelphia, aided in this work by giving many helpful suggestions.

Greene and Conner streets.

ABSTRACT OF DISCUSSION

DR. FITZ FEAR, JR., Lincoln, Neb.: Having spent twelve years with Dr. Orr, I am expert on the smell in osteomyelitis. Dr. Wallis has shown how to eliminate considerable of the odor. By inverting the chemical or biologic change from one of putrefaction to one of fermentation he has done away with the odor which has been one of the objectionable feature. Albee showed a good many years ago that *Clostridium perfringens* was often found in osteomyelitis wounds but did not cause symptoms. He cultured these organisms and injected them into laboratory animals and was able to show that they were virulent. The outstanding thing to me is that a wound will stand the presence of large numbers of different types of bacterial anaerobes and aerobes without causing symptoms. As far as I know no one has made a study of what happens in such a wound from the standpoint of the healing of the wound. We have had studies of wound healing in normal operation but is the change that occurs in the wounds that are treated in this manner due to the development of granular membrane or to the lymphatic stasis produced by immobilization as suggested by Trueta? I think that his work has been admirable and will probably be a great boon in the treatment of this condition since it has been shown for many years that the petrolatum itself is not an important part of the treatment. If the wound is packed open with any type of gauze, paraffin or any other substance the effect is the same provided the postoperative care is carried out. One of the most important factors in our clinic in minimizing the odor and Dr. Wallis has already stressed that is the time which elapses between changes of dressing. In our cases, when we operate primarily, we feel that the odor is kept to a minimum by dressing these patients not oftener than every six weeks. The worst offenders are the mixed tuberculous infections such as we have in Indians and Dr. Wallis has explained just why that is the case.

DR. LENOX D. BAKER, Durham, N. C.: The theory explaining the odor associated with the Orr therapy is apparently well founded. The authors have presented a method of combating

this factor and I for one intend to use the method. It is to be regretted that time did not allow a reading of the entire paper, as some of the most interesting findings have been omitted in the presentation. Dr. Wallis mentioned another treatment—the local use of sulfonamides and primary closure, which, when successful, results in healing by first intention without drainage. The discussor surveyed the American Academy of Orthopaedic Surgeons as to the results from the local implantation of the sulfonamides in acute compound fractures, in acute osteomyelitis, in old compound fractures with infection and in chronic osteomyelitis following saucerization. The results in the latter two groups should be of interest and are presented in the accompanying tables. This survey indicates that the desired method of treating chronic osteomyelitis is thorough surgery, a local sulfonamide and primary closure.

Results in Old Compound Fractures with Infection

	Total	Healed	Infected
Open reduction plus chemotherapy	47	30	17
Sulfanilamide	14	7	7
Primary closure	7	3	4
Open method	7	4	3
Sulfathiazole	3	1	2
Primary closure	20	17	3
Open method	13	6	7

* All had drains twenty-four to forty-eight hours.

Results in Chronic Osteomyelitis

	Total	Healed	Infected
Surgery plus chemotherapy	74	54	20
Sulfanilamide	11	7	4
Primary closure	4	4	0
Open method	7	3	4
Sulfathiazole	63	47	16
Primary closure	41	6	35
Open method	22	11	11

Seven later healed, three had severe flareups.

DR ALVAN D. WALLIS, Philadelphia. With regard to Dr. Baker's mention of the relation between healing and odor, I have no comments to make, because I can't say that we have observed that relationship particularly. As far as liquefaction and autolysis and their relation to the healing process are concerned, I am not convinced that there is any connection. We don't feel that odor is in any sense necessary or that the processes which produce odor contribute anything to the healing of the wounds.

Composition of the Body—Approximately 99 per cent of the mass of the human body is made up of six elements: oxygen (65), carbon (18), hydrogen (10), nitrogen (3), calcium (2) and phosphorus (1). The remaining 1 per cent is distributed between potassium (0.35), sulfur (0.25), sodium (0.15), chlorine (0.15), magnesium (0.05), iron (0.004) and smaller amounts of iodine, fluorine, copper, zinc, and so on. The protoplasm of other animals and of plants is made up of essentially the same elements but in different proportions. Evidently the elementary composition of protoplasm tells us very little as to what it is. In protoplasm these elements are combined into proteins, fatty substances, carbohydrates, many other organic molecules, water and mineral salts. However, such substances individually and when mixed in the laboratory are dead material. In order that living protoplasm may result, these various compounds must be brought together and organized in a highly specific way, and at present this can be accomplished only through the agency of other living protoplasm.—West, Edward S. *Physical Chemistry for Students of Biochemistry and Medicine*. New York: Macmillan Company, 1942.

CLASSIFICATION AND MEDICAL RELATIONSHIPS OF HYPERTENSIVE-ALBUMINURIC PREGNANCY

A. J. B. TILLMAN, M.D.

Assistant Consultant, the Sloane Hospital for Women
NEW YORK

There are three concepts of the etiology of hypertensive-albuminuric pregnancy: (1) that it is the same disease and has the same etiology as in the nonpregnant state; (2) that it is the same disease as in the nonpregnant state plus additional disease directly due to the pregnancy; and (3) that it is a disease primarily due to the pregnancy.

1. If the first is true, then any classification of hypertensive-albuminuric pregnancy should be identical with the classification of such disease in the nonpregnant state. There are certain adherents to this belief and at times I have been one. The difficulty in accepting this view is the occurrence in pregnancy of the typical convulsive state called eclampsia, the clinical picture of which is not reproduced under any circumstances in the nonpregnant state.

Herrick has suggested that this syndrome may be regarded as "acute hypertension," but proof of this is lacking, and until it is supplied eclampsia must be regarded as an entity in itself.

With this exception, the clinical picture of all types of hypertensive-albuminuric disease in pregnancy is found in the nonpregnant state.

2. In addition to so-called preeclampsia and eclampsia there are other clinical states which arise in pregnancy, such as the sudden appearance and disappearance of hypertension, edema and albuminuria which may or may not be explainable on the same basis as in the nonpregnant state. It is therefore possible that these conditions are modified by something peculiar to the pregnancy itself.

3. The third concept that hypertensive-albuminuric pregnancy is something peculiar to pregnancy itself is in my opinion also tenable.

The possibility of concept 2 lies in the fact that, while hypertensive albuminuria and edema occur in the pregnant state as they do in the nonpregnant, they may be modified, as for instance by their exaggeration very often acutely, and by their retrogression when pregnancy is over.

Concept 3 implies that these states are something peculiar to pregnancy and have no relation to similar conditions in the nonpregnant state.

Is there to be a classification according to the clinical syndrome presented or should the classification be one based on essential underlying disease? If the former, it is possible to place cases as one sees them during pregnancy in certain more or less arbitrary categories. The final classification of the individual case, however, may be possible only after a varying period of follow-up or after necropsy.

An illustration of this is case 1.

CASE 1—A woman presented hypertension, albuminuria and edema in the last trimester of pregnancy. She was examined repeatedly both in pregnancy and in the postpartum period. Finally, about one and one-half years after her pregnancy, hypertension still persisting it was noted that her kidneys were abnormally large, and appropriate x-ray studies revealed polycystic kidneys.

Read before the Section on Obstetrics and Gynecology at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1942.

In the presence of a gravid uterus the difficulties of diagnosis and classification are obvious

The following is another illustrative case

CASE 2—A S., a white woman aged 29 a quartipara quartigravida, was admitted to Sloane Hospital April 17, 1923 Five years before (1918), when she was 24, her systolic blood pressure had been noted as 230 Two years later (1920) she had a miscarriage at three months Nine months following,

The modification of nonpregnant hypertensive albuminuric disturbance in pregnancy causes us difficulty in classification Hypertension is generally aggravated, occasionally unaffected and rarely decreased Whereas hypertension alone was present prior to pregnancy, albuminuria appears in the last trimester and disappears with delivery Infrequently it persists The albuminuria of chronic nephritis, pyelonephritis, congenital malformed kidney or of the calcareous diseased kidney, while rarely unaffected almost always becomes massive Edema if present prior to pregnancy almost always increases These adverse changes occur earlier when renal insufficiency is present but are commonly abrupt and generally occur in the third trimester

A classification of hypertensive-albuminuric pregnancy must therefore include the causes of hypertension and albuminuria seen in the nonpregnant person Hypertensive-albuminuric pregnancy may merely reflect vascular and renal disturbances which have no relationship to pregnancy

The time relationship of classification is important and in itself has furnished a major difficulty, this relationship must take into consideration the time of the recognition of disease For example, the observer sees patients who for one reason or another have blood pressure readings and urinalysis done prior to pregnancy Abnormalities are then definitely known and their behavior in pregnancy is readily noted But these patients are relatively few By far the greater number by reason of the absence of symptoms, are regarded as having been normal unfortunately absence of symptoms prior to the onset of pregnancy or even a normal blood pressure and urine in the early months of pregnancy does not permit of the assumption that the blood pressure and urine were normal before the onset of pregnancy Hence if patients are seen for the first

Chart 1—A case of very mild hypertension preceding pregnancy illustrating how hypertension can disappear in the second trimester of pregnancy

the miscarriage she had an induced labor at six and one half months for convulsions severe hypertension edema and severe albuminuria Two years later (in October 1922) in early miscarriage took place In the present pregnancy the blood pressure persisted with some minor fluctuations at 210 systolic and 120 diastolic for six months Albumin was negligible and edema was absent Nonprotein nitrogen was 27.8 mg per hundred cubic centimeters of blood urea nitrogen 13.5 mg, uric acid 2.5 mg, sugar 95 mg and cholesterol 223 mg, urine was sterile One week prior to delivery albumin increased and edema of the face appeared The patient was delivered of a full term child by cesarean section For the next six years she was followed in medical clinics where she was considered an example of hypertensive vascular disease She died suddenly of a heart attack in 1929 Permission for autopsy was not given

Consider the difficulties in diagnosis and of ultimate classification of these patients The second patient's condition was an example of hypertensive disease prior to pregnancy the convulsive state appearing in the second pregnancy In her fourth pregnancy criteria of hypertensive disease were present for six months and then, shortly before delivery, evidence of the preconvulsive state appeared Nearly all these months had been spent in the hospital, so it is very likely that the convulsive state was prevented by therapy While the convulsion is emphasized for purposes of classification its absence does not change the underlying disease We therefore remain with a classification today which might be one of therapy rather than of disease

The first case illustrates the fact that for purposes of study every means at our command should be undertaken to establish underlying disease Clinical classification may be correct in the vast majority of cases of hypertensive-albuminuric pregnancy, but prolonged study may be necessary to determine the fundamental cause in every case

Chart 2—A case of more severe hypertension preceding pregnancy illustrating how hypertension can disappear in the major portion of the pregnancy

time late in pregnancy, the significance of elevation of blood pressure and albuminuria can easily be misinterpreted

The same picture is described in chart 1 can be simulated in pregnancy completely by the person who was entirely normal prior to pregnancy Is one to regard the cases of preexisting disease and those in which the first manifestation occurred during the pregnancy as one and the same? Our evidence at Sloane

Hospital favors this view on the basis of a series of 188 cases reported by Herrick and myself. But whether they should be identically classified in pregnancy is a moot question.

Cases are seen in which the hypertension is more severe. For example, in the former case hypertension preceded pregnancy, in the latter the blood pressure was normal one year prior to the first pregnancy. From the eighth month on, however, there was little difference between the 2 cases, in the absence of information prior to the pregnancy, one might easily classify the two as identical cases but they are decidedly different.

Classifications have been suggested which depend on the behavior of hypertension and albuminuria in the postpartum period. This point of view immediately causes trouble. Postpartum observations vary for many reasons. The duration of hospital observation is variable, and consideration must be given to racial, social and economic factors, in addition, complications such as shock and infection, particularly kidney infections, produce changes in blood pressure and in the urine. The ultimate conclusion may depend on whether the period of postpartum observation has been ten days, two weeks six weeks, three months, one year or a lifetime.

Should one therefore have a temporary classification in pregnancy followed by a reclassification at a later date? A procedure of this sort calls for an elaborate system of records, patients will not or cannot all return, and so only a small percentage of the patients may be classified. The work is tedious and most of it unnecessary, and still it must be done in every case if the record is to be of value statistically. Obviously other than for purposes of study such a method is impracticable.

Further difficulties in classification are encountered when the criteria of hypertensive-albuminuric pregnancy are reviewed. These are hypertension, albuminuria, edema and convulsions. The various classifications depend on the interrelationship of these findings. The time of appearance, degree, duration and rapidity of resolution after delivery furnish the bases.

The convulsions may precede but almost always follow hypertension, albuminuria and edema and while its specific causation is not understood it is just an additional manifestation of the disturbance. Its dramatic nature, however, permits clearcut demarcation in classification.

Another difficulty is in classifying the normal and the abnormal pregnancy. The blood pressure reading arbitrarily adopted as normal in most clinics varies from 130 to 140 systolic and 90 diastolic. Minor degrees of hypertension are frequently seen on two or three occasions during pregnancy. The rises may be transient, particularly when noted early in the middle trimester. Only when sufficient time has elapsed can one say whether the pregnancy is normal or abnormal, or whether these rises are functional or pathologic. Similarly, albuminuria appears in slight degree in a number of pregnancies which never exhibit further disturbance. Albuminuria of this type as yet is unsatisfactorily explained. Such albuminuria is probably innocuous but its presence is disturbing and always leads to the suspicion of abnormal pregnancy. Edema is even more difficult to interpret. Nearly every pregnant person at some time or other during pregnancy

more commonly in the last trimester, has edema. When unsupported by other evidence, it is generally disregarded but the question remains: Is it abnormal or physiologic?

Hypertension, albuminuria and edema are symbolic of numerous widespread disturbances. The common occurrence of these diseases in the nonpregnant state influences the way in which hypertension, albuminuria and edema in pregnancy are regarded.

When the patient is seen for the first time in the last trimester of pregnancy and has hypertension, albuminuria and edema, singly or in combination, it may be impossible to say whether there was an underlying disorder prior to the pregnancy or whether the symptoms were solely the result of the pregnancy. The syndrome is identical in the 2 cases. This last statement is, of course, open to criticism, but I think that the evidence still favors the belief that acute hypertensive-albuminuric pregnancy with or without convulsions can occur in the absence of as yet demonstrable preexisting disease. This conclusion is based on careful clinical examination, chemical analysis, urologic examination, including bacteriologic examination, intravenous and retrograde pyelography and necropsy studies. How can these events be reconciled? On the one hand prior vascular and renal disease, on the other apparent absence of previous disease, and yet in pregnancy the same clinical syndrome ultimately appears. It is impossible to interpret the final clinical picture as other than an effect of pregnancy, which in the 1 case aggravates and in the other initiates the process.

This discussion seems to have wandered from an attempt at classification but it is designed to show that an ideal classification seems at present to be impossible. As an example, the advance of chronic nephritis frequently, not always, is more vicious in pregnancy, the label "chronic nephritis in pregnancy" is incomplete. When hypertensive disease in the last trimester of pregnancy goes on to the preconvulsive state should the syndrome be set down as hypertensive disease or as the preconvulsive phase or preeclampsia, individually or as a combination. The preeclamptic picture probably results because hypertension was present and it is this very picture that differs from the hypertensive disease prior to the pregnancy. These changes should be represented in a classification.

In considering the last aspect of the influence of nonpregnant disease on hypertensive-albuminuric pregnancy one must arbitrarily exclude hypertensive-albuminuric disturbances arising prior to the pregnancy. These excluded, is there evidence to support the thesis that hypertensive-albuminuric disturbances arise as the result of pregnancy? The preconvulsive and convulsive hypertensive-albuminuric syndromes have been discussed. Between the diseases acquired prior to pregnancy and the convulsive state of pregnancy there are many variations of hypertension-albuminuria and edema arising in pregnancy which demand clarification. The greatest number of cases consist of pure hypertension. This may arise at any time in pregnancy, generally occurs in the last part of the second or early in the third trimester and increases in severity as term is approached. The exception to this behavior is a sudden severe hypertension which persists in the absence of albumin and edema. This is similar in onset with many of the full blown preconvulsive or preeclamptic groups and is always a

potential menace in the pregnancy. Until delivery has been effected a diagnosis cannot be made. Whereas in some the condition may clear at that time other patients will persistently exhibit hypertension thereafter. I have followed a sufficient number of these patients to know that they fall into the hypertensive-vascular disease group in later life.

The classification of this type of case and similar examples of hypertension which appear and disappear with pregnancy has always been difficult. If the term "toxemia of pregnancy" is used in designating hypertensive-albuminuric pregnancy these states unequivocally should be placed in such a category. Many examples of the preconvulsive state or preeclamptic state in pregnancy exhibit hypertension as the first manifestation. Later edema, albumin and secondary features occur. If this syndrome is compared with the former it is hard to avoid the many similarities. Until delivery has been effected convulsions must be feared as the former state may merge into the latter. Similarly until delivery has occurred classification cannot be established. One must conclude that two or more syndromes may arise as a result of pregnancy and terminate in a convulsive state or that the many syndromes which arise as a result of pregnancy are identical fundamentally.

180 Fort Washington Avenue

PROTEINURIA IN TOXEMIA OF PREGNANCY

WILLIAM J. DIECKMANN, M.D.

SYLVIA KRAMER, Ph.D.
CLINICAL

Proteinuria or albuminuria in pregnant patients should always be regarded as evidence of some renal abnormality. It is one of the triad of signs (hypertension, albuminuria, edema) of preeclampsia and the appearance of proteinuria should suggest the possibility of eclampsia developing. The appearance or increase of protein in the urine of patients with hypertensive disease or chronic glomerulonephritis should always suggest impending fetal death which is usually due to well defined placental infarction, retroplacental hematoma or abruptio placentae.

Studies by Addis and his co-workers indicate that the urine of normal persons contains from 0.02 to 0.06 Gm of protein in twenty-four hours. The constant excretion of larger amounts is abnormal.

Studies by Elden and Conney as well as by us indicate that these amounts are unchanged during normal pregnancy.

Benign proteinuria does occur in a nonpregnant person but a thorough examination of the renal function and urine must be made before the case is so diagnosed. We have a small number of patients who have had persistent proteinuria during pregnancy without any other manifestation of vascular or renal disease.

The following notes concerning 6 patients who had proteinuria before pregnancy with no obvious cause are of interest. One patient had a diagnosis made of physiologic albuminuria by the medical service in 1931

but since then she has had three toxemic pregnancies and now has persistent hypertension. Another had proteinuria in 1933 which was ascribed to dehydration from vomiting. The correct diagnosis at that time could have been established with an Addison count. The first and last pregnancy, in 1935, was complicated by hypertension of 220 systolic and 150 diastolic, hematuria and the other manifestations of recurrent acute glomerulonephritis. The patient did not return in 1938 and in view of the severe hypertension and low renal function has probably died. A third patient was eventually found to have a bilateral pyonephrosis due to ureteral strictures from nephrolithiasis. A fourth patient had the first pregnancy interrupted because of hypertension but a subsequent pregnancy was uneventful. Her renal function is a low normal. The remaining 2 have had uneventful pregnancies and their renal function is a low normal. Obviously proteinuria in both pregnant and nonpregnant patients must always be considered as due to a renal disorder.

Theobald reports protein in the urine in the following groups of normal persons: college girls 24 per cent, postoffice girls 17 per cent, chamberwomen 8 per cent and women medical students 54 per cent. He states that the possibility of contamination from a vaginal discharge rarely occurs. He presents no data for pregnancy but states that most antepartum clinics had that the incidence of proteinuria is very low in the first six months of pregnancy.

Burd catheterized 1000 pregnant patients and found that 57 per cent had proteinuria. The incidence of proteinuria in our antepartum patients was 20 per cent. We have made more than 1100 urea clearance examinations mostly on patients who have or have had toxemia and 45 per cent of the urines which were all obtained by catheter contained protein.

Lighty-two per cent of our toxemic patients had a 2 plus proteinuria for at least one day, or a 1 plus or more for at least three days. Ninety-five per cent of the patients with severe preeclampsia and 89 per cent of those with severe hypertensive disease had proteinuria.

Proteinuria usually occurs during labor, especially in the latter is long or the contractions are of long duration and frequent. The cause is the muscular exercise. Protein in large amounts can be found sometimes in the urine of patients who have had extensive hemorrhage especially abruptio placentae. Infection in the urinary tract may also cause albuminuria.

The concentration of proteins in the urine range from a negligible amount up to a maximum of 5 per cent. As a rule when the concentration exceeds 1 per cent the volume of urine is extremely small. The twenty-four hour excretion of protein in the urine usually ranges from 0.2 to 3 Gm. When the daily excretion exceeds 3 Gm the duration is short because the clinical condition usually becomes so severe that intervention is necessary. A daily excretion of more than 5 Gm of protein in the urine for ten days or more should suggest a nephritis or nephrosis as such a large excretion rarely if ever occurs in preeclampsia.

Several studies have been made of the urinary albumin-globulin ratio. In patients with nephritis the ratio is usually 6 or more to 1. Patients with eclampsia excrete a large amount of globulin and the ratio is 2 or 3 to 1. In patients with nephrosis and nephritis analysis of the urinary protein for cystine and tyrosine or analysis by electrophoresis indicates that in some

patients the composition of the urinary protein is different from that usually found. In these patients the composition of the serum protein is also altered.

Chesley found that in chronic glomerulonephritis and in nephrosclerosis there was a constant filtration of protein. However, in preeclampsia and eclampsia the filtration of protein was extremely variable.

The protein in the urine is lost through the glomerulus, and in cases of renal disease in which many glomeruli are still functioning the concentration and twenty-four hour excretion of protein in the urine will be relatively large. However, as the number of functioning glomeruli grows less the amount of protein in the urine decreases sharply, thus occasionally giving the impression that the kidney lesion is improving or has actually been cured, whereas if renal function tests are made decided impairment is usually found.

Kellogg in 1924 stated that there was some relation between proteinuria and abortion, stillbirth and abruptio placentae in hypertensive patients. He stressed the importance of proper diet and rest together with the interruption of the pregnancy several weeks or months before term.

Young has presented data concerning the "toxemic sequence" that is repeated abortions and stillbirths associated with toxemia of pregnancy. According to him the incidence of abortion, premature labor, abruptio placentae and stillbirth is 10 per cent in normal patients and 23 per cent after a toxemia. Fifteen per cent of the pregnancies in our clinic after nonconvulsive toxemia terminate without a living baby.

Gibberd has always emphasized the importance of proteinuria during pregnancy. He states that

If a patient with albuminuria is treated carefully over a long period and induction of labor is performed just soon enough to avoid eclampsia there is a tendency to regard such treatment as an obstetric triumph made possible by the great clinical acumen of the obstetrician. Actually it is often a grave obstetric blunder in that as a result of the prolonged albuminuria an incurable chronic nephritis may develop.

We do not agree with Gibberd that the cause of the chronic nephritis is the result of the prolonged proteinuria. We have evidence that patients who have persistent hypertension or albuminuria, or a recurrence of toxemia in a subsequent pregnancy have a vascular disease as the basis and that they would have these conditions irrespective of the duration of the toxemia. We do not believe that true preeclampsia or eclampsia causes a permanent vascular or renal disorder.

Theobald suggests that the albumin associated with pregnancy could be accounted for by the lordosis, the diminished thoracic capacity associated with the latter months of pregnancy and the weight of the uterus. He thinks that albuminuria per se bears no relationship to the toxemia of pregnancy except that disturbances of metabolism and diet are factors in the causation of both conditions.

Krieger and Rome¹ studied the effect of a toxemic pregnancy in relation to subsequent pregnancies. They divided their patients into the following groups: (1) those suffering from albuminuria A, in which protein was observed in the urine for one day only, (2) those suffering from albuminuria B, in which albumin was observed in the urine for two to four days, (3) those suffering from albuminuria C, in which protein was present in the urine for longer than four days in the

ante partum and post partum periods and in which there frequently was hypertension and edema, (4) those suffering from typical preeclampsia associated with symptoms, (5) those suffering from chronic nephritis with evidence of permanent renal damage.

Krieger and Rome found that proteinuria of less than four days' duration has little if any effect on the pregnancy or on future pregnancies. However, if it persists longer than four days the incidence of abortion, premature birth, stillbirth and toxemia increases sharply and the likelihood of these conditions recurring in a subsequent pregnancy is also sharply increased. From 20 to 30 per cent of the pregnancies resulted in abortion, 3 to 30 per cent of the babies were premature and 10 to 20 per cent were stillborn. From 35 to 40 per cent of the patients with severe toxemia had a recurrence in subsequent pregnancies. Sixty-four per cent of 651 pregnancies resulted in 418 living children.

We wished to determine the importance of proteinuria in toxemic patients. Patients with preeclampsia, hypertensive disease and chronic renal disease (glomerulonephritis or nephrosclerosis) were divided into groups according to table 1. Patients not at term who had constant proteinuria for two weeks and then had the pregnancy terminated were considered as having proteinuria for a period of more than four

TABLE 1.—Distribution of Patients with Preeclampsia, Hypertensive Disease and Chronic Renal Disease

Amount of Proteinuria	Duration of Proteinuria
+ or ++ daily	2 to 4 weeks and over 4 weeks
++ constant and +++ or ++++ for at least 1 week	2 to 4 weeks and over 4 weeks

weeks. This grouping may and probably does account for some of the slight inconsistencies, especially in the group of patients with severe proteinuria for more than four weeks. Since the chief differences were found between the groups of slight and of severe proteinuria the divisions according to the duration were omitted. Differences related to the duration of the albuminuria would have been more striking had we used a shorter period than two weeks. The comparisons are made primarily between slight proteinuria of two weeks or longer (preeclampsia and hypertensive disease) and severe proteinuria for two weeks or longer, a constant 2 plus and a 3 plus to 4 plus for at least one week.

From 1931 to 1941 we have had 2,320 patients or 86 per cent of all deliveries with nonconvulsive toxemia of pregnancy. This study is based on 526 patients which is 23 per cent of the toxemic patients and 1.94 per cent of the total deliveries. Fifty per cent had preeclampsia, 42 per cent had hypertensive disease and 8 per cent had chronic renal disease. Similar figures for all of our toxemic patients are 38, 53 and 5 per cent respectively.

The means for the ages are those usually reported: preeclampsia 27, hypertensive disease 30 and nephritis 31.

The preponderance of primiparas in the preeclamptic group is normal. The relatively high incidence of primiparas in the hypertensive "severe" group may be the result of faulty diagnosis (table 2).

Section B in the table contains data based on a history of previous abortions, stillbirths, premature

¹ Krieger, V. and Rome, R. M. J. Australia 1: 397 (May 17) 1941.

deliveries and toxemia. The high incidence of 93 per cent in the patients with severe proteinuria and hypertension is worth noting. Likewise, the patients in both the mild and severe albuminuric groups with hypertension have an increased incidence of stillbirths and recurrent toxemia. These data bear out the well known belief of the increased fetal mortality in patients with recurrent toxemia.

TABLE 2—Data on Five Hundred and Twenty Six Toxemic Patients

	Proteinuria				Ne- phritis
	Mild		Severe		
	Pre- clampsia	Hypertensive Disease	Pre- clampsia	Hypertensive Disease	
1 Number of patient Primiparas per cent	144 (7)	16 17	117 (9)	57 36	41 1
2 History of previous abortion, per cent	44	44	10	—	0
History of previous still births per cent	4	1	1	16	6
Total fetal mortality per cent	45	20	11	91	76
3 Blood pressure mm Hg					
Systolic mean	161	170	163	176	171
Diastolic mean	101	111	111	118	117
4 Edema per cent					
Abent	1	1	15	5	9
++ or +++	2	20	6	2	6
+++ or ++++	—	11	9	3	3
5 Symptoms per cent per cent	51	41	4	2	16
Retinal disease per cent per cent	54	46	0	77	1

The means for the systolic and diastolic blood pressure are given for each group. The hypertensive and nephritic patients have a much higher mean than the patients with preeclampsia. These pressures are no higher than those found in patients without proteinuria.

From 80 to 85 per cent of the patients had 1 to 2 plus edema, approximately 10 per cent had no edema and the remainder had severe edema. We were surprised to find so high an incidence of edema in the hypertensive groups.

Thirty-one to 56 per cent of the patients had one or more of the symptoms associated with toxemia, headache being the most common. The tendency for the patient to have symptoms seems to parallel the amount and duration of the proteinuria.

The percentage of patients having abnormal retinal findings are given in section E. The hypertensive patients, as one would expect, have a higher percentage of retinal disease than the preeclamptic group. The amount and duration of the proteinuria bore no relation to the number of patients in the hypertensive group having retinal disease.

Data as to the management of the pregnancy are given in table 3. The high incidence of induction of labor and cesarean section is striking in all groups, but especially in the hypertensive and preeclamptic with severe albuminuria. These incidences are much higher in patients with proteinuria than in those without it. As would be expected, the morbidity of the toxemic patients is 23 per cent as compared with the average for the hospital of 7.9 per cent.

The distribution of weights of the fetuses are given in table 4. As the degree of proteinuria and severity of the condition increases, the number of fetuses weighing more than 2,500 Gm decreases. The mean weights

of the babies in the various groups are of interest. It is only in the group of patients with severe proteinuria and in the nephritic group that the mean weight of the baby is well below that of the average. Since the pregnancy of many of these patients was terminated before term, it might account for the decreased weight. However, the general experience is that in patients with persistent and severe albuminuria the birth weight of the fetus is always less than the normal for that period of pregnancy.

Table 4 contains data concerning fetal mortality. The incidence of stillbirths and neonatal deaths is much higher among the patients with severe albuminuria than those with a mild involvement. Even in the group with mild albuminuria the total fetal mortality is more than twice that of the whole hospital. If one compares the total mortality among patients having albuminuria with the total fetal mortality for all toxemic patients it becomes apparent that the major portion of fetal deaths occurs in those toxemic patients who have proteinuria of several weeks' duration. The patients with albuminuria lasting for two weeks or more comprise 23 per cent of all patients with nonconvulsive toxemia, but 37 per cent of the total deaths occurring in toxemic patients were found in the albuminuric group.

There are 5 patients with severe hypertensive disease among whom pregnancy occurred twenty times, with only four or 20 per cent living babies. These were delivered before term by cesarean section at thirty-two to thirty-six weeks gestation. One patient with three pregnancies has had no living children.

The incidence of abruptio placentae in the preeclamptic group was 1.1 per cent, in the hypertensive group 5.4 and in the nephritic group 7 per cent. Sixteen per cent of the preeclamptic group and 22 per cent of the hypertensive group had well defined maturation of the placenta. Approximately 6 per cent of all patients were anemic.

The means for the serum protein concentration were calculated whenever there were at least fifteen determinations. In both hypertensive and preeclamptic groups the means varied from 6.3 to 6.6 before delivery.

TABLE 3—Onset of Labor or Termination of Pregnancy

	Proteinuria per cent				Ne- phritis
	Mild		Severe		
	Pre- clampsia	Hypertensive Disease	Pre- clampsia	Hypertensive Disease	
Spontaneous	74	47	46	44	16
Induction	12	3	8	33	19

Hysterotomy				4	6
Therapeutic abortion					7

and from 6.8 to 7.3 after delivery. The means for the urea clearances in the hypertensive groups were approximately 74 per cent both before and after delivery. These figures do not indicate any depletion of the serum protein concentration or any renal damage.

Approximately 50 per cent of the patients with hypertensive disease and 80 per cent of the patients with preeclampsia had a normal blood pressure on discharge from the hospital. Most of the patients in the hypertensive group had hypertension when seen three to six months post partum.

Peckham in 1933 attempted to correlate the fetal mortality with varying amounts of protein in the urine. The data in table 5 are based on Peckham's figures as well as on our own. It indicates a definite relationship between the number of abortions and fetal deaths and the increasing amounts of protein in the urine. We believe that the determination of the twenty-four hour excretion of protein in the urine is of far greater value than the determination of the concentration.

The data in table 6 illustrate the value of twenty-four hour determinations of protein and sodium chloride in the urine. Small amounts of protein cannot be detected with a qualitative test if the volume is large. Compare data for March 17, 19 and August 5, 18 and 20. The chloride determination reveals how well the patient is cooperating in her elimination of salt from the diet. The chloride and sodium intakes will usually be less than 15 and 0.8 Gm respectively if the urinary chloride is less than 1.8 Gm or less than 3 Gm as sodium chloride in twenty-four hours. A sodium poor diet is of value if edema is present but of little or no value in the treatment of the hypertension.

TABLE 4—Fetal Weight and Mortality

A	Proteinuria				
	Mild		Severe		No proteinuria
	Pre-eclampsia	Hypertensive Disease	Pre-eclampsia	Hypertensive Disease

Total fetal mortality—proteinuria per cent	7	16	15	35	35
Total fetal mortality—all toxemic patients per cent	6	7	17	37	48

Vascular and renal diseases are not the only causes of repeated abortion or stillbirths. One patient had a vaginal hysterotomy because of severe toxemia. There were two subsequent abortions attributable to the absence of the internal os. A repair of the cervix resulted in the birth of a live baby. Another patient with no evidence of vascular or renal disease had five pregnancies, all being breech or transverse position and all terminating in stillbirths. Examination revealed a bicornate uterus, with well developed horns but a comparatively little uterine body, thus the fetal head had to be in one horn and the breech in the other. The fetal deaths were due to the hazards of delivery. Syphilis is another cause of repeated stillbirths or premature deliveries. Hypertensive disease is no contraindication to antisyphilitic treatment.

All patients with persistent hypertension and/or proteinuria should have a thorough examination of the urinary system (microscope examination and renal function test as well as cultures of the urine, pyelograms and cystoscopic examinations in selected patients), ophthalmoscopic examination and an attempt to determine the etiology of the hypertension (blood pressor and depressor tests).

The causes of proteinuria have been enumerated. In pre-eclampsia and eclampsia the vascular spasms in the renal vessels are the cause. There is no evidence

now available to account for the vascular spasms. Certainly the amount of proteinuria does not parallel the height of the blood pressure. The hypertensive patient will usually have albuminuria after the twenty-eighth week of pregnancy when the blood pressure also begins to increase. The latter phenomenon is more likely to be the cause of the proteinuria than vice versa.

Our treatment is as follows. The fetuses of patients with prolonged proteinuria and especially of patients

TABLE 5—Abortions and Fetal Mortality (per Cent) and Proteinuria

Proteinuria Gm /100 Cc	Abortions	Fatal Mortality	Total Mortality
None	2	4	6
Trace	1	7	8
Less than 1.9 Gm	3	8	11
2.4-9 Gm	4	15	19
≥ 9 Gm	9	23	31

with hypertensive disease are always small for the period of gestation. If we see these patients in the first trimester intravenous injections of 500 cc of a 20 per cent solution of dextrose are given three times daily for seven to ten days, in an endeavor to increase the size of the fetus and placenta. The patients are also urged to be constantly eating hard candy in an attempt to maintain a high blood sugar. In a small series this therapy has resulted in the birth of fetuses that were larger than previous ones.

The patients are told to rest in bed for ten hours at night and one hour in the morning and afternoon. These periods of rest are increased later in pregnancy. Phenobarbital or potassium bromide may be used as needed.

The diet should contain approximately 2,000 calories. It is adjusted so that the maximum weight gain is 7 to 8 Kg for the whole pregnancy, by limitation primarily of the fats. The weight gain should be less than 225 Gm ($\frac{1}{2}$ pound) a week. The protein intake should be 80 Gm or more, derived chiefly from meat, milk and eggs. We have relied on the proper selection of foods for an adequate vitamin intake rather than on the ingestion of pure vitamins. Vitamin E or alpha

tocopherol has not been of value in preventing fetal death from placental infarction or abruptio placentae.

The basal metabolic rate of patients with severe hypertensive disease is usually negative or even below normal and does not increase despite the stimulus from the pregnancy and thyroid medication. These patients take 0.06 to 0.2 Gm of thyroid daily throughout the pregnancy.

If edema occurs, the diet must contain only a negligible amount of sodium and chloride. Salt or baking powder cannot be used in the preparation of foods or

the baking of bread and rolls. Salt-free butter is used. No crackers, pretzels, cheese, sausages, salted meats and fish, prepared salad dressings, canned soups, beer or "patent medicines" for the relief of gastric distress are permitted. There is a very low sodium content in flour, cream, macaroni, sugar, potatoes, squash, parsnips, lettuce, kidney beans, tomatoes and most vegetables and cereals. Eggs, meat, milk, beets, brussels sprouts, corn mushrooms, peas and spinach are reasonably low in sodium content and may be consumed in moderate amounts. Boiling the meat will remove most of the sodium. The broth must be discarded.

Watch the water balance (weight). Ammonium chloride in 1 Gm. gelatin capsules is given eight times a day for five days and repeated after a five day interval. If symptoms of cardiac decompensation are present the fluid intake is limited to 500 to 1,000 cc.

Oliguria or anuria is treated by the intravenous injection of 500 to 1,000 cc. of a 20 per cent solution of dextrose two or three times a day. Occasionally 500 to 800 cc. of a 30 per cent solution is necessary to produce diuresis. If there is cardiac decompensation 100 to 200 cc. of a 50 per cent solution is used.

The general experience is that the loss of protein in the urine cannot be prevented by increasing the protein intake. If possible, it should be balanced. The determination of the twenty-four hour excretion is important for its prognostic value.

Cerebral, visual and gastrointestinal symptoms are treated by sedation, intravenous injections of dextrose solution and delivery.

Renal function tests are of little value in the preeclamptic patients but are of prognostic value in patients with other types of toxemia. Ophthalmoscopic examination is of value if pathologic changes are found but normal conditions do not rule out the gravity of the toxemia.

Usually after several observations one is able to diagnose the toxemia as one of preeclampsia or hypertensive disease. Treatment depends in part on the diagnosis. If the diagnosis is preeclampsia there is a possibility of eclampsia developing. If it is hypertensive or renal disease, eclampsia is not likely to occur but there is a possibility of fetal death, especially after thirty weeks because of placental infarction, retroplacental hematoma or abruptio placentae.

Since preeclampsia is caused by the pregnancy and since hypertensive and renal disease are usually made worse by pregnancy, it seems obvious that termination of the pregnancy may be necessary. The following criteria are indicative of severe toxemia. The patient must be carefully observed, and if labor does not ensue termination of the pregnancy is usually necessary.

Group A Criteria—The systolic blood pressure is constantly 170 mm. of mercury or shows a persistent daily increase.

The proteinuria exceeds 5 Gm. in twenty-four hours or the qualitative test of the twenty-four hour urine is 3 plus.

The weight gain exceeds 100 Gm. a day.

Severe edema occurs suddenly.

Group B Criteria—Cerebral, visual or gastrointestinal symptoms arise.

Oliguria, anuria or hematuria occurs.

Jaundice develops.

The blood nonprotein nitrogen is 50 mg. or more per hundred cubic centimeters.

The pulse rate is 120 or more.

Edema of the lungs or cyanosis is present.

The blood shows an increasing concentration, as indicated by an abnormally high or increasing hemoglobin, cell volume, serum protein concentration or specific gravity.

The advisability of terminating the pregnancy is dependent on the duration of the gestation, the severity of the symptoms and signs and the condition of the cervix.

Gestation of twenty-six weeks or less should be terminated if more than one of the criteria listed are present or if there is no appreciable improvement after seven days of adequate treatment.

Gestation of twenty-seven to thirty-one weeks should be treated medically until the thirty-second week, unless some B signs develop or the A signs persist despite treatment or increase in degree.

Gestation of thirty-two to forty weeks, if B signs are absent, should be treated medically until the cervix is "ripe" when induction of labor will be successful. If the A signs increase in degree or if any of the B signs appear, the pregnancy should be terminated either by (1) rupture of the membranes and/or insertion of a bag or (2) cesarean section if the cervix is uneffaced.

Our results indicate that the careful medical management of the toxemic patient if begun early enough will usually prevent further increase in the severity of the symptoms and signs until the cervix is "ripe." This means that the cervix is effaced and dilatable in the primipara or soft and partly dilated in the multipara, as determined by vaginal examination, and that labor can usually be successfully induced by rupture of the membranes.

The patient who does not respond to treatment or has been neglected is treated by rupture of the membranes and/or the insertion of a bag if the cervical canal is less than 2 cm. long or if there is no effacement by cesarean section under local anesthesia.

There is general agreement that the severely affected preeclamptic patient with the various symptoms should be treated as if she had eclampsia with great emphasis on immediate delivery, because the average maternal mortality for eclampsia is 13 per cent and for nonconvulsive toxemia 17 per cent.

Vascular collapse or shock may develop in patients with severe hypertensive disease either before delivery or within the first twenty-four hours post partum. Death may occur. If the condition occurs, the parturient canal must always be examined for a possible rupture with internal hemorrhage. Intravenous injections of 500 cc. of a 20 per cent solution of dextrose are of immediate value to be followed by transfusions of serum or blood. Pressor drugs are also of value.

CONCLUSION

Proteinuria for a period of two weeks or more in hypertensive pregnant patients is accompanied by a sharp increase in the incidence of abortion, stillbirth and abruptio placentae.

Albuminuria per se is no indication for termination of the pregnancy. Other evidence of vascular or renal disorder must be present.

The total uncorrected fetal mortality among all of the patients with nonconvulsive toxemia was 11 per cent. Thirty-seven per cent of these fetal deaths occurred among the group of patients with proteinuria of at least two weeks' duration who comprised only 23 per cent of all patients with toxemia.

RELATIONSHIP OF THE HORMONES
TO THE TOXEMIAS OF
PREGNANCYHOWARD C TAYLOR JR MD
NEW YORK

The alterations that take place in the maternal physiology with the onset of pregnancy may be ascribed to one cause or to a combination of causes. The more important include the pressure effects of the enlarging abdominal mass, the changes produced on the maternal circulation by the development of the vascular system of the placenta, the demands made by the growing ovum and by the reproductive organs of the mother for nutritive materials and perhaps the need for disposal of certain waste products or antibodies produced in the developing fetus. Finally, there are the so-called sex hormones formed in the placenta which from a period early in pregnancy are found in the maternal body fluids in concentrations far above anything ever observed in the nonpregnant state.

Specific toxemia, or 'hypertensive albuminuria' is a disease which apparently can develop only in women and only under the peculiar conditions of pregnancy. It is evident that any factor contributing to the development of what is characteristic of the physiology of pregnancy must receive at least passing consideration in the search for the cause of such a disease. Each of the factors listed in the foregoing paragraph has in fact at one time or another been held responsible. With the recognition of the effects of the sex steroids on extragenital functions these hormones have received understandable attention in recent studies of the etiology of toxemia of pregnancy.

Two conceptions as to the exact relationship of the hormones to the development of toxemia of pregnancy appear to have emerged as a result. 1 According to one view, an abnormality in quantity or in the exact chemical nature of one of these hormones is present in the woman with toxemia of pregnancy. Such a conception implies a fairly direct causal relationship and holds out the possibility of a successful hormone therapy. 2 According to the second view there is some other direct cause of the disease but the placental hormones by the physiologic alterations they produce in the maternal organism greatly modify its course or clinical characteristics. The evidence for and against these two conceptions forms the essential material for this contribution to the symposium.

THE HORMONES OF PLACENTAL ORIGIN AS THE
CAUSE OF TOXEMIA OF PREGNANCY

Quantitative studies on the serum and urine content of chorionic gonadotropic substance of estrogens and of pregnandiol have been reported from many laboratories in the last few years. Full agreement has not been arrived at, but the results begin to indicate certain probable trends. These may be briefly summarized as follows.

Chorionic gonadotropic substance is said to be elevated in the urine and the blood serum of patients with toxemia. A recent compilation of their work made

by the Smiths¹ showed that in 67 cases of normal pregnancy there were no instances of elevated chorionic gonadotropin in the serum, while in 100 cases of pre-eclampsia and of eclampsia about 85 per cent presented abnormally high values. Although a few dissenting opinions have appeared, including a report by Browne, Henry and Venning,² and our own work at the New York University Medical College,³ the majority of studies have tended to confirm the finding of an elevated chorionic gonadotropic substance in cases of toxemia.

The excretion of estrogens has been reported by several workers as being low in cases of severe toxemia and with this finding we are in full agreement. Fractionation of the estrogens has led to the further observation¹ that in cases of toxemia there is an increased percentage of estrogenic activity accountable to estradiol, a decreased amount to estriol and a low or absent estrone content.

Chart 1—Effect of progesterone therapy on blood pressure, urine volume and proteinuria in a patient with toxemia of pregnancy.

Pregnandiol, the excretion product of progesterone, is low in the urine of toxemia patients according to a number of reports. This appears to be a fairly consistent finding although exceptions certainly occur.¹

The total excretion of androgens or more strictly the 17-ketosteroids, appears from a few reported studies in the literature and some unpublished determinations of our own to be little changed by either pregnancy or toxemia. A few strikingly high values have however been recorded but nothing has been done to discover whether the special compounds of the 17-ketosteroid group are abnormal in their quantitative relationships to each other.

2 Browne, J. S. L., Henry, J. S. and Venning, Eleanor H. Urinary Excretion of Prolan, Estrin and Pregnandiol in Normal Pregnancy and in Early and Late Pregnancy Toxemias. *J Clin Investigation* 17:503 (July) 1938.

3 Taylor, H. C. Jr. and Scadron, E. N. Hormone Factors in the Toxemias of Pregnancy. *Am J Obst & Gynec* 37:963 (June) 1939.

There is then in toxemia a tendency to low estrogen and pregnandiol excretion, probably a high chorionic gonadotropic content of serum and urine and certain changes in the relative amounts of the constituents of the estrogenic fractions. The essential question remains

Chart 2—Effect of progesterone therapy on excretion rates of estrogen and pregnandiol in a patient with toxemia of pregnancy

as to whether these abnormalities are evidence of a specific causative hormone imbalance or are simply secondary manifestations resulting from a disorder having a quite different cause

In accordance with the first view, it has been suggested that toxemia of pregnancy is preceded by a pro-

Chart 3—The effect of parturition on sodium balance in normal pregnancy

gressive progesterone and estrogen deficiency, is closely associated with a rapid destruction of the estrogens and is perhaps due to some toxic product resulting from such destruction. The second view, it being recalled that these hormones are produced by the placenta and in the case of the steroids, subjected to various chemical alterations in the liver, holds that the hormonal abnor-

malities in the urine are simply the result of the pathologic changes that are present in the placentas and livers of many preclampsic patients. The evidence at hand does not permit the present exclusion of either hypothesis

On the apparent assumption that the symptoms of toxemia of pregnancy are the direct result of a hormone deficiency numerous attempts have been made to treat the disease by the administration of estrogens or progesterone. Promising results have been reported by White and Hunt⁴. The Smiths⁵ speak of the preventive value of the hormones and report a temporary benefit in the treatment of some patients but on the whole are guarded in their conclusions

Treatment of 9 patients with toxemia of pregnancy in the wards of Bellevue Hospital with large doses of progesterone, estradiol benzoate or a combination of these substances has not led us to believe that their administration has any specific effect on the course of the disease. The patients on whose course this opinion is based were all treated for at least one week by bed rest, sedatives and a restricted sodium and water intake before the endocrine therapy was commenced. Progesterone to amounts of 450 mg and estradiol benzoate

Chart 4—The effect of parturition on sodium balance in toxemia of pregnancy

in total doses of 180,000 rat units did not exert any evident effect, as indicated by blood pressure, weight change, daily urine volume or proteinuria. There was, furthermore, little evidence of a consistently altered rate of hormone excretion. The effect of treatment on 1 typical case is graphically shown in charts 1 and 2

The least that can be said is that neither estrogen nor progesterone in any dose yet employed has shown itself to be specific in the alleviation of the toxic signs of pre-eclampsia. This fact is a small additional point against the direct causative relationship of a hormone imbalance to toxemia

THE HORMONES OF PLACENTAL ORIGIN AS MODIFYING FACTORS IN THE CLINICAL PICTURE OF TOXEMIA

Without a disorder of the hormones being the immediate cause of toxemia of pregnancy, the possibility remains that these substances are important factors in the disease. A preexisting susceptibility to vascular or

renal disease as has been alleged to be present in certain cases of toxemia, might become clinically evident under the hormonal conditions of pregnancy. On the other hand any renal or vascular disease as a result of the modifying action of the placental hormones might assume clinical characteristics during pregnancy quite different from those appearing in the same disease in the nonpregnant.

With these possibilities in mind, the particular aspects of the physiology of pregnancy attributable to the placental hormones must be separated from those due to other factors. In the investigation of these relationships the period from ten days before labor until ten days thereafter becomes important, because within this time occurs the enormous change from the high hormone concentrations of pregnancy to the low values of the puerperium. We have therefore devoted particular attention to the study of sodium balance and of renal function during the days before and after delivery, examining each in relation to normal and toxemic pregnancy and to the effects of the hormone withdrawal resulting from the loss of the placenta.

Sodium and Water Balance.—The edema of normal pregnant women commonly evident in the swelling of

Chart 3.—The effect of parturition on sodium balance under postpartum estrogen administration.

the feet and ankles is the clinical expression of a tendency to retain water and ultimately to a diminished capacity to excrete sodium. In cases of toxemia there is usually a further sodium and water retention and a greater degree of edema.

It has been shown experimentally that the administration of an estrogen or progesterone to laboratory animals is followed by retention of sodium and the so-called menstrual edema of normal women has been attributed to these hormones.⁶ On the basis of these observations it might be expected that the great concentrations of estrogen and progesterone found in normal pregnancy would be accompanied by an increased sodium and water retention and perhaps by mild edema.

In studies made by us⁷ we have noted the following correlations between estrogen concentration and sodium balance (charts 3, 4, 5 and 6). In the normal puerperium there is a pronounced loss of sodium on the third, fourth and fifth days—the days when estrogen

excretion is first at low levels. In 1 case in which the estrogen level fell with the death of the fetus several days before delivery the sodium balance became negative before delivery. In several cases the puerperal loss of sodium has been apparently prevented or reduced by

Chart 6.—The effect of parturition on sodium balance after antepartum fetal death.

the artificial administration of estrogens or progesterone during these days when the patient's own hormones are disappearing. In patients with toxemia the postpartum loss of sodium is of course usually much greater, and this cannot be prevented by any quantity of hormone which we have yet been able to administer.

On the basis of these studies it appears to us that the sodium and water retention of normal pregnancy is due largely to the steroid hormones manufactured by the placenta. It is doubtful whether the increased sodium retention of toxemia is simply an increase in this effect. On the other hand the already present tendency of all

Chart 7.—The effect of parturition on renal function in two typical cases of toxemia of pregnancy: one with clinical cure and one with residual hypertension after delivery.

pregnant women to retain sodium and water as a result of estrogen and progesterone probably contributes to the edema of preeclampsia and perhaps even to the convulsions of eclampsia if the latter are due to cerebral edema. In this indirect manner at least the placental hormones have a relationship to toxemia.

⁷ Taylor H. C. Jr., Warner R. A. and Welsh Catherine A. The Relationship of the Estrogens and Other Placental Hormones to Sodium and Potassium Balance at the End of Pregnancy and in the Puerperium. *Am. J. Obst. Gynecol.* 38: 746 (Nov.) 1939.

Renal Function—Clinical signs of disturbance in renal function in cases of toxemia consist in the proteinuria, the edema and the hypertension. In the majority of cases these signs disappear rapidly during the first days or weeks of the puerperium changes which might again conceivably be due to the disappearance of the hormones of pregnancy.

Several recent laboratory studies have indicated that the hormones have a considerable effect on kidney structure and function. Hypophysectomy and castration in male animals cause a reduction in the size of the kidney. The male hormone produces an increase in weight of the rat and mouse kidney and recent unpublished studies in our laboratory have shown that in the dog testosterone causes a great increase in the maximal capacity of the tubules to excrete diodrast. The action of estrogens is less definite but Korenchewsky⁸ has suggested that the effect may be even a toxic one. These investigations show at least that substances of the general class to which certain of the placental hormones belong do have an effect on the kidney.

In the last few years investigations have been made in several laboratories on renal function in normal and toxemic pregnancy by means of inulin and diodrast clearances which measure the glomerular filtration rate and the renal blood flow. Our own studies have paid particular attention to contrasting conditions immediately before and after delivery.⁹ The glomerular filtration rate and renal blood flow appear normal in uncomplicated pregnancy and in a given individual are unaffected by the fall in hormone concentrations after delivery. In the presence of the hypertension of toxemia there was found before delivery a normal or even elevated blood flow—an unexpected finding since a reduced blood flow has been found to be characteristic of essential hypertension. After the delivery of such toxemic patients, however, if their hypertension persists the renal blood flow as measured by diodrast clearance rapidly falls. Certain factors present during pregnancy apparently maintain an adequate renal blood flow in spite of the hypertension, but these are withdrawn with delivery, and renal ischemia results. These factors are conceivably hormonal in type.

This consideration of the possible relationship of the hormones of placental origin to the toxemias of pregnancy is clearly only the beginning of the subject. Other possibilities, previously reviewed³ can be only briefly referred to here. (a) The posterior pituitary has been held responsible as the source of excessive quantities of antidiuretic and vasopressor hormones. The report of such materials in the blood and urine of eclamptic patients has been much disputed. (b) The anterior pituitary gland has been studied in patients dying of eclampsia and histologic changes supposed to be specific described. A variety of hormone substances supposedly derived from the anterior pituitary gland have also been reported as present in the blood of preeclamptic patients. (c) The adrenal has received somewhat less attention but low values of corticotrophic hormone and an absence of the usual adrenal hypertrophy of pregnancy have led to the claim of a cortical deficiency in toxemia. Treatment of toxemia with cortical hormones has of course been tried. (d) A lowered basal metabolic rate has been observed in some cases of toxemia. This has led

to a recent hypothesis that a relative hypothyroidism sets off a series of events beginning with hypochloremia which, progressing through placental endarteritis leads to placental infarcts and eclampsia.

SUMMARY

To return to the hormones of placental origin and their relationship to toxemia, one may say the following in summary:

1 That these substances, which evidently play such a profound role in establishing what is characteristic of the physiology of pregnancy, should have an influence on a disease such as toxemia, which occurs only in pregnancy, seems almost certain.

2 That an imbalance between the estrogens, progesterone and chorionic gonadotropic substance or a toxic product of their disordered metabolism is a direct cause is not yet established.

3 That the physiologic effects of the presence of these hormones should modify the clinical picture of the disease particularly as regards salt and water retention, and perhaps as regards certain aspects of kidney function seems probable.

542 Park Avenue

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. TILMAN, DR. DIECKMANN AND KRAMER AND DR. TAYLOR

DR. W. W. HERRICK, New York. To what point have we advanced in our study of this problem? We recognize the results of renal insufficiency in the pregnant woman. The factor of safety in the kidney must be largely abolished before pregnancy brings disaster. We are agreed on the effect of polycystic kidney and other serious congenital anomalies and of pyelitis and pyelonephritis when these have progressed to the point of notable renal destruction. Most of us are agreed that the milder grades of pyelitis and pyelonephritis are of little or no consequence in the production of toxemia. The second great group of toxemias comes under the heading of vascular disease with hypertension. Most observers with experience are agreed that the effect of pregnancy in the woman with established hypertension is bad. In some quarters the statement is made that women with essential hypertension can safely undertake pregnancy. I believe this doctrine is dangerous and injudicious. While there are exceptions it is the rule that the patient with established hypertension does badly in pregnancy. The third great group of toxemias—eclampsia and preeclampsia, is most difficult to orient in relation to vascular disease. It is my opinion that we pay too much attention to the convulsion. It is dramatic, it is arresting but it is not specific. It does not merit a separate classification. We see similar convulsion in nephritis, in vascular disease and in numerous other conditions. If I were to argue that eclampsia and preeclampsia have nothing to do with vascular disease, I would place emphasis on the peculiar pathologic changes of eclampsia. While it is true that in rare examples of hypertension and of hyperthyroidism one sees changes in the liver which are quite like those found in eclampsia they are extremely uncommon. It is difficult to explain the peculiar pathologic changes in eclampsia on any basis other than that of a specific disease. The other features of eclampsia, however, the renal picture, the hypertension, the albuminuria, the edema, certain cellular alterations in the kidneys and other organs may be found in vascular disease at some stage. The foundation of future study of the toxemias as of vascular disease must be twofold. First pathologic histology. It is disappointing that the more recent studies of the toxemias of pregnancy have paid so little attention to this phase of the subject. It should be possible to get adequate material for the comparative study of the pathologic tissue changes of vascular disease and of the so-called specific toxemias. The second basis of progress is physiology. At present advance in either problem—hypertension or toxemia of pregnancy—is arrested by the limitations of our knowledge of physiology.

DR J ISFRED HOFBAUER, Cincinnati The profound constitutional transformation incident to gestation, particularly during its latter months, is the result of the hyperplasia and associated overactivity of the endocrine chain thyroid adrenal cortex-pituitary, the adrenal changes representing the response to the pituitary (basophilic) stimulus. To these factors must be added the abundance in the blood of estrogenic and gonadotropic hormones and certain split products of proteins which in the aggregate act to effect inherent vascular hypertonus and augmented responsiveness to vasopressin. On two recent occasions attention was focused on the consistent occurrence in the normal placenta of remarkable quantities of acetylcholine as a potent vasodilator through its restraining influence on the tone of the vascular musculature (*West J Surg* 49 615 [Nov] 1941; *Cincinnati J Med* 23 107 [May] 1942). During gestation a delicate vascular balance is thus maintained. Another phase of the subject concerns the actual demonstration of placental acetylcholine deficiency and low choline content of the blood in the late toxemia of pregnancy. Stated as succinctly as possible dislocation of the equilibrium between blood pressure activating and restraining principles peculiar to normal gestation with a resultant unopposed effect of vasopressin on the arterioles and on the hypothalamic nuclei, appears to constitute the real determinant in the pathogenesis of the disorder. This new concept is based on established facts and has the unqualified endorsement of preeminent American physiologists. For details and certain therapeutic implications may I refer to my paper in the *American Journal of Obstetrics and Gynecology* (26 311 [Sept.] 1933) and the two other articles quoted.

DR A J RONGY, New York The treatment of eclampsia still belongs in the domain of the art of medicine not to the science of medicine. The most significant statement made by Dr Tillman was that many women who suffer from hypertension during pregnancy develop circulatory symptoms in later life. I attended many school teachers at a time when a greater number of school teachers remained unmarried. I had the opportunity to observe many of these women married and unmarried, of the same ages and social standing and strata. I observed that the same constitutional type that developed eclampsia or hypertension during pregnancy suffered from circulatory disturbance when unmarried and usually died in the sixth decade of life. I feel that the trained obstetrician can readily anticipate the type of person likely to develop toxemia during pregnancy. I do not know whether this is a universal experience, but I have found that a woman who is long necked and has a slightly enlarged thyroid seldom if ever gets eclampsia, but the woman whom we ordinarily classify as short necked, with wide pelvic bones fat and chubby is most likely to get some form of hypertension during pregnancy. These women have to be watched and carefully regulated. I have laid stress not so much on the hypertension or on the amount of albumin as on the constitutional reaction. A woman may have a blood pressure of 160 or 170 she may have a slight increase in albumin but as long as she has no constitutional reaction such as loss of appetite, headache itching of the skin or some slight epigastric pain that woman is not dangerously ill and I am willing to carry her along in her pregnancy. If, however the constitutional reaction to hypertension—whether it is 140 or 160—is great, that woman may get a convulsion at any time and should be treated accordingly. I should like to ask Dr Dieckmann why he performed twenty four cesarean sections in cases of mild hypertension. It does seem to me that if a woman is suffering from only a mild hypertension the obstetrician has plenty of time to induce labor and that there is no necessity for doing a cesarean section.

DR WILLIAM J DIECKMANN, Chicago Dr Rongy questioned the incidence of 24 per cent delivery by cesarean section in the patients with slight proteinuria. Many of these patients had pronounced hypertension, retinal pathologic changes and impaired renal function without much evidence of proteinuria. In other words, the "slight" and "pronounced" in this series had no relation to the severity of the toxemia. Many patients have definite evidence of severe toxemia with little or no albumin in the urine.

CASUALTY ANESTHESIA IN ENGLAND

K C MCCARTHY, MD

Anesthetist to Toledo Mercy Flower and Lucas County Hospitals
TOLEDO, OHIO

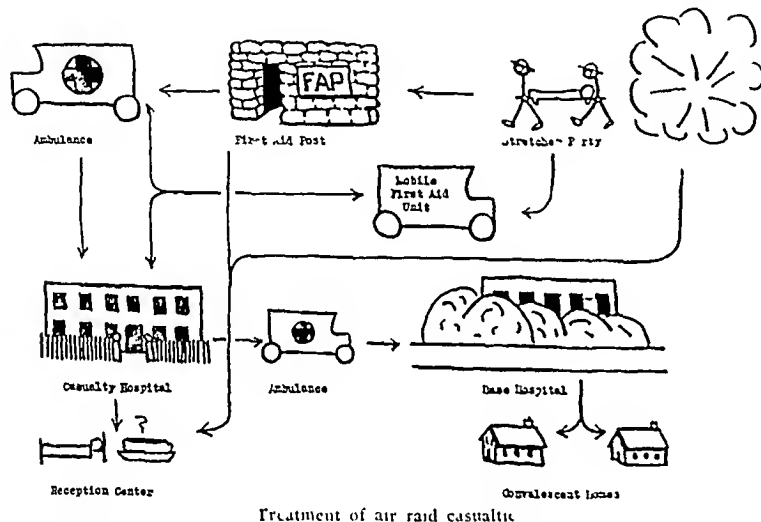

During the past year I served as anesthetist with the American Hospital in Britain Ltd, a volunteer organization financed by the British War Relief Society and headed by Dr Philip D Wilson, surgeon in chief of the Hospital for Ruptured and Crippled. Eight months were spent in England, during which time there was an opportunity to observe the methods and agents used not only by the services but also by civilian agencies in the treatment of casualties from air raids and other manifestations of enemy action. While bomb injuries were numerous, quite a number of casualties were seen as a result of automobile and motorcycle accidents for which the blackout was a contributing factor. There were also injuries from airplane crashes and the ordinary accidents suffered by troops in training. Gunshot wounds were comparatively rare.

To appreciate the place of anesthesia in casualty surgery it is necessary that one study the organization of the medical services set up to deal with air raid casualties and other emergencies. The patient is first seen at the first aid posts. These are established in locations convenient to main thoroughfares, are protected by sandbags and are prominently marked so that walking wounded can find them in the blackout. Most factories and stores have their own posts staffed by employees. The public ones are manned by volunteer workers trained and supervised by a local physician, and receive casualties by stretcher from the scene of action. The stretcher parties are assisted by rescue squads, who have special equipment for digging into debris, moving and cutting beams and girders, and otherwise extricating victims who have been buried by falling buildings.

Little medical treatment is given at the first aid post. Diagnoses are made and the patients are classified as immediate or delayed. Temporary splints and dressings to fix fractures and control hemorrhage are applied and the patients moved immediately to casualty hospitals by motor ambulance. If the first aid post is destroyed or overwhelmed with work, mobile units operating from the hospitals are available to replace them.

The casualty hospitals are the usual civilian hospitals of the community 'cleared for action'. All patients are able to be moved are sent to the country, and no patients are accepted except in real emergencies. The top floors are evacuated, as they are most vulnerable and operating theaters are set up in the basement protected by sand bags and with emergency water supplies and lighting equipment. Minor injuries are treated immediately and the patients evacuated to reception centers where they can be fed and housed temporarily. Air attack causes serious injuries, of which compound fractures and the 'crush syndrome' are probably the most common. The mortality is high over 40 per cent. Energetic treatment is required for shock. Special resuscitation wards are established where these cases can be segregated under the care of trained personnel. Clothes are removed, warmth is supplied by hot water bags and blankets, and the foot of the bed is raised on 'shock blocks'. Morphine is given freely.

Oxygen, especially useful in the treatment of pulmonary edema subsequent to "blast," is administered by a simple flowmeter, bag and face mask apparatus. In some places the B L B inhaler is used. There seemed to be an adequate supply of blood and natural plasma, constantly replenished from donor centers established in most of the larger cities. Plasma is used in the treatment of simple shock, hemorrhage is combated with blood transfusion. After shock has been treated, emergency surgery can be performed. Abdominal injuries are operated on as soon as possible. Nitrous oxide-oxygen supplemented with minimal ether is the commonest agent used and a high degree of skill is necessary for obviously many patients are still in poor condition from loss of blood and shock. Wounds and burns are debrided under general anesthesia. Intravenous pentothal sodium is commonly used for these cases, it may be supplemented with nitrous oxide if it appears that the duration of the operation may necessitate an unduly large dose. Shock is considered to contraindicate the use of open ether or spinal analgesia.

The usual surgical team comprises an attending and a house surgeon, anesthetist, two nurses and two orderlies. If work is heavy it may be necessary for the anesthetist to supervise two or even three tables. They are set up side by side in the same room for greater convenience. The major work is done by the attending surgeon, who is on duty one day weekly, though if there is great pressure of work other men will turn out and help. The staff will usually stay on duty till all urgent cases have been dealt with. Sometimes this means over twenty-four hours' continuous work. The house men care for most of the minor cases and do much of the routine work.

The casualty hospital must concentrate on life saving measures and regard reconstructive surgery as of minor importance. Therefore patients are evacuated to the base hospitals in the country as soon as they can be moved, often only two or three days after operation. Beds must not be allowed to become filled or it would be impossible to accommodate an additional flood of casualties, and complete evacuation might be necessary at any time because of fire or severe damage.

Most city hospitals have established annexes in the country to which patients are sent for safety and to provide a place where the training of students and nurses can continue. Some famous London institutions have had to abandon their buildings in the city com-

pletely but are thus able to preserve their organization for activity after the war. These base hospitals have been set up in large houses, mental institutions and some new "hut" hospitals. The ideal base hospital is completely equipped for all types of cases with emphasis on reconstructive surgery. Besides general surgical services there may be special units for chest surgery, brain surgery, orthopedics, peripheral nerve and laryngeal surgery.

The government considers that the civilian casualties from enemy action are entitled to as good treatment as the armed forces and for this purpose has established the Emergency Medical Service under the Ministry of Health. Many of the base hospitals are administered by this service and have a full time staff of attending physicians and surgeons, specialists and house men. An attempt is made to have the staff drawn from the city hospital, from which most of the cases are sent so that there may be continuity of treatment. Service cases are admitted to the base hospital from ships, naval hospitals and camp first aid stations. They receive the same treatment as the civilians. As a matter of fact, the methods used by the Emergency Medical Service do not differ essentially from those employed by the Royal Army Medical Corps or the Naval Medical Department. The Royal Air Force, on the other hand, treats its own personnel.

The American Hospital in Britain was assigned to work at Park Prewett Hospital in Hampshire. It is the base hospital for a sector comprising the cities of Portsmouth and Southampton and southwestern London, and most of our casualties came from the urban areas. It is a huge rambling affair, formerly a mental hospital, consisting of some thirty-five two story brick buildings connected by roof but not walled passages. Each building accommodates about 50 patients in large wards.

In addition to three general surgical services, there were special plastic and orthopedic units. Each service has its own wards, house staff and operating theater and anesthetist. In addition there were two part time anesthetists for relief. The house surgeons did many of the more minor cases for a great many anesthetics were given for changing casts and painful dressings.

A typical service would have six wards and an operating theater. This was a large windowless octagonal room that had been used for hydrotherapy. It had tiled walls and linoleum on the floor. The baths and showers had been removed and modern sterilizing and operating room equipment installed. There was a mobile x-ray machine and an adjacent dark room. The theater was piped for nitrous oxide and oxygen under low pressure, and a crane hung to the wall carried the tubing containing the gases over the heads of nurses and orderlies right to the gas apparatus. Quite a wide range of movement was allowed.

There were two Boyle's machines in each operating theater so that one anesthetist might supervise two tables should that need arise. These are much like Foregger's except for dry flowmeters. These are of two types. The Coxeter, with a vertical cylindrical perforated tube in which a rather closely fitting float rises in proportion to the gas flow, the gas escaping through holes below the float. This type of meter is not capable of sufficiently fine adjustment for accurate basal oxy-

gen flow and makes the carbon dioxide absorption technic difficult. The other type, the Rotometer, has a tube tapering toward the lower end. The float is held in suspension by the gas which escapes around it, the height being proportional to the flow.

Most machines had no carbon dioxide absorber, a rebreathing bag being mounted on the head of the apparatus. When an absorber was supplied, it was of the circuit type with by-pass. The gases were led in at the mask. The whole apparatus was mounted on a table, on which there were yokes so that small cylinders could be used in an emergency, or to supplement the larger ones on the piping system.

Ether is vaporized by various methods. The gases may be bubbled through the ether. A wick type vaporizer, similar to that used on American apparatus, is supplied with the carbon dioxide absorber. Or the gases may be passed into the ether chamber through a U shaped tube, the open end of which is covered by a movable cylinder. Depressing this cylinder forces the gases to travel through more ether before escaping and thus increases the concentration. Drip attachments with sight feed are also used. Many vaporizers have water jackets to improve their efficiency. A chloroform bottle is supplied, the gases being bubbled through the liquid.

Gas is plentiful, though there is often some delay in filling orders because of transportation difficulties. There is also a shortage of cylinders, especially the smaller sizes, as no new ones are being made, and many were said to have been lost at Dunkirk. Cyclopropane or ethylene is not supplied by the government. The former can be obtained though the cost is high. Supplies must be ordered well in advance of requirements.

Intravenous pentothal sodium is a favorite anesthetic for minor cases and has practically replaced evipal, which at one time enjoyed great popularity in England. Pentothal is also being used for more prolonged operations, such as brain surgery, and a number of ingenious devices have been made for the prolonged and continuous administration of this drug.¹

Adriani² has suggested that there are theoretical objections to the administration of pentothal sodium when the patient has been taking sulfanilamide and related drugs. Sulfanilamide was given very extensively, both locally and by mouth, and it would have been almost impossible to use pentothal had it been limited to untreated cases. Pentothal was used freely in spite of this medication without harmful effects, and it is suggested that these dangers are exaggerated. Nitrous oxide plus ether was the most popular anesthesia for routine major surgery, although sometimes nitrous oxide was reinforced with chloroform, and even both chloroform and ether were used. Open ether was very seldom seen, though sometimes it was used to maintain anesthesia after induction had been carried out with Clover's inhaler or, more rarely, ethyl chloride. Spinal analgesia was seldom employed. When used the favorite drug seemed to be light percame (nupercaine) in 1:1,500 solution, the technic that of Howard Jones.³ Local or regional blocks were very rare.

Endotracheal tubes were passed in most abdominal cases. It gives one a great feeling of security to know that respiratory obstruction cannot occur when supervising two or more anesthetics at the same time. Magill's tubes were used, passed through the nose, the larynx being exposed with Magill's laryngoscope, a conventional U shaped instrument. Magill's forceps was usually used to insert the tube. The throat was usually packed with gauze, as the use of a cuffed tube through the nose presents difficulties. In many cases 1 per cent percame (nupercaine) in petrolatum was used as a lubricant to the catheter. It was felt that the local anesthetic effect was valuable, as it permitted very light anesthesia without coughing.

General anesthesia was used for plastic surgery, and endotracheal methods were essential. Intubation was usually done through the mouth unless that was the seat of operation. These operations were often quite prolonged, but light anesthesia and the carbon dioxide absorption technic minimized the amount of ether used and recovery was usually prompt. The line of incision was infiltrated with a dilute epinephrine solution to diminish hemorrhage, which is annoying when one is doing fine work.

Chest surgery is done by special teams which may be stationed at a base hospital, or may be mobile, traveling about as needed from hospital to hospital. An effort is made to have these units attend all major chest cases. Cyclopropane is supplied for anesthesia, the technic used has been described in detail by Nosworthy,⁴ anesthesiologist to a mobile chest unit.

Anesthesia for major neurologic surgery varied somewhat in different clinics. The methods that seemed to be most popular were either tribromethanol in amylene hydrate supplemented with endotracheal nitrous oxide-oxygen and ether, or local infiltration plus intravenous pentothal sodium. The volume of cranial surgery was said to be much less than during the last war.

The medical situation seems to be well in hand at the present time. Certainly there is no shortage of doctors, though they may be distributed badly. No doubt some physicians are overworked in areas that are overcrowded with many evacuees. On the other hand, doctors in the larger cities from which many people have been moved often have little to do. This is particularly true of London, where the fashionable Harley Street practitioner has suffered severely and numbers have been glad to accept salaried positions with the Emergency Medical Service. The amount of work thrown on the medical profession as a result of the war has been much less than anticipated. Epidemics were foreseen as the result of the disruption of sanitary facilities and overcrowding in air raid shelters but so far none have materialized. Casualties from enemy action, in the services and the civilian population have been far less than expected and, owing to the improvement in shelters and air raid precautions generally, will probably not be any worse in the future. Many physicians have been taken into the army, but approximately half are engaged in administrative, clerical and office duties that could be done as well by nonmedical personnel. To me it seems as if the profession in Britain has risen to the occasion and has the situation well in hand.

Oxygen, especially useful in the treatment of pulmonary edema subsequent to "blast," is administered by a simple flowmeter, bag and face mask apparatus. In some places the B. L. B. inhaler is used. There seemed to be an adequate supply of blood and natural plasma, constantly replenished from donor centers established in most of the larger cities. Plasma is used in the treatment of simple shock, hemorrhage is combated with blood transfusion. After shock has been treated, emergency surgery can be performed. Abdominal injuries are operated on as soon as possible. Nitrous oxide-oxygen supplemented with minimal ether is the commonest agent used and a high degree of skill is necessary, for obviously many patients are still in poor condition from loss of blood and shock. Wounds and burns are debrided under general anesthesia. Intravenous pentothal sodium is commonly used for these cases, it may be supplemented with nitrous oxide if it appears that the duration of the operation may necessitate an unduly large dose. Shock is considered to contraindicate the use of open ether or spinal anesthesia.

Treatment of air raid casualties

The usual surgical team comprises an attending and a house surgeon, an anesthetist, two nurses and two orderlies. If work is heavy it may be necessary for the anesthetist to supervise two or even three tables. They are set up side by side in the same room for greater convenience. The major work is done by the attending surgeon, who is on duty one day weekly though it there is great pressure of work other men will turn out and help. The staff will usually stay on duty till all urgent cases have been dealt with. Sometimes this means over twenty-four hours' continuous work. The house men care for most of the minor cases and do much of the routine work.

The casualty hospital must concentrate on life saving measures and regard reconstructive surgery as of minor importance. Therefore patients are evacuated to the base hospitals in the country as soon as they can be moved, often only two or three days after operation. Beds must not be allowed to become filled or it would be impossible to accommodate an additional flood of casualties, and complete evacuation might be necessary at any time because of fire or severe damage.

Most city hospitals have established annexes in the country to which patients are sent for safety and to provide a place where the training of students and nurses can continue. Some famous London institutions have had to abandon their buildings in the city com-

pletely but are thus able to preserve their organization for activity after the war. These base hospitals have been set up in large houses, mental institutions and some new "hut" hospitals. The ideal base hospital is completely equipped for all types of cases, with emphasis on reconstructive surgery. Besides general surgical services there may be special units for chest surgery, brain surgery, orthopedics, peripheral nerve and facio-maxillary surgery.

The government considers that the civilian casualties from enemy action are entitled to as good treatment as the armed forces and for this purpose has established the Emergency Medical Service under the Ministry of Health. Many of the base hospitals are administered by this service and have a full time staff of attending physicians and surgeons, specialists and house men. An attempt is made to have the staff drawn from the city hospital, from which most of the cases are sent so that there may be continuity of treatment. Service cases are admitted to the base hospital from ships, naval hospitals and camp first aid stations. They receive the same treatment as the civilians. As a matter of fact, the methods used by the Emergency Medical Service do not differ essentially from those employed by the Royal Army Medical Corps or the Naval Medical Department. The Royal Air Force, on the other hand, treats its own personnel.

The American Hospital in Britain was assigned to work at Park Prewett Hospital in Hampshire. ABSTRACT OF DISCUSSION

A L TYNES, Major, Medical Corps Washington, D C We are indebted to Dr McCarthy for this paper describing his personal experiences in an English casualty hospital during the big blitz. He has given us an account of the types of anesthetics used and a clear picture of the medical organization set up to care for such air raid emergencies. It is interesting to note how closely the organization of these first aid posts and casualty stations follows that of our own army battalion aid stations, surgical hospitals and evacuation hospitals. I believe that intravenous anesthesia is playing an ever increasing role in war surgery. Several years ago while at Walter Reed Hospital I had the privilege of introducing intravenous pentothal sodium to the Army as an anesthetic agent. The Surgeon General now places such importance on this type of anesthesia for wartime use that a manual is being prepared for general distribution to all medical officers describing in detail its technique and limitations. I am surprised to hear Dr McCarthy say that spinal anesthesia was seldom used. In our army we have come to rely more and more on this procedure, particularly for operations below the diaphragm. It is my belief that spinal and intravenous anesthesia will play the greatest role in pain relief for the American forces during this conflict. Many of you are wondering what opportunity the medical anesthetist will have to follow his specialty should he enter the United States Army. At present each army station and general hospital of 500 beds or more is training surgical teams to be organized into tactical units which will be sent overseas as rapidly as possible. I will cite the auxiliary surgical group. This group contains twenty-four surgical teams, six splint teams, six shock teams, six gas teams, four neurosurgical teams, four thoracic surgical teams, four plastic maxillofacial teams and four miscellaneous specialist teams. Each of the twenty-four surgical teams is made up of one surgeon, one assistant surgeon, one anesthetist, one scrub nurse and one surgical technician. The other teams are organized along similar lines. This auxiliary surgical group is only one of our many tactical medical organizations. The Army needs trained medical anesthetists and whenever they are available every effort will be made to use them in this specialty.

DR S LEROY SMITH, Rochester, N Y. I should like to mention a few points with regard to the technical problems of anesthesia and analgesia under war conditions. It seems to me that the first aid casualty station would be the one most important place for the use of common horse sense. A great many of the accident cases are similar to the week end auto and motorcycle accident cases that pour into our emergency department and they are amenable to the same practical treatment. Perhaps the first aid post, which is mentioned in Dr McCarthy's paper as a distributing center, would be the ideal place for administering the initial doses of morphine or other analgesics. Perhaps adequate instruction could enable the physician at the first aid post even to give intravenous morphine to the patient for quick prolonged analgesia. This would enable them to be moved to the casualty station or base hospital. In the prompt relief of pain some of the basic causes of vasomotor changes might be eliminated and shock brought more rapidly under control. The handling of the casualty stations themselves seems to be well controlled and well organized for most efficient service. There is only one possible point for discussion in the handling of patients in these stations, and that is the use of nitrous oxide and ether for emergency operation. It is my firm belief that the lives of these critically ill patients would be less in jeopardy under proper cyclopropane anesthesia than under nitrous oxide. The high concentration of oxygen so necessary in proper handling of shock or borderline shock cases is impossible to maintain with nitrous oxide anesthesia, whereas with cyclopropane the forced concentration of oxygen is ideal for this purpose. Of course I recognize that skilled observation is necessary to ward off the occasional profound postoperative 'cyclo shock' syndrome that all of us have met. This, however, is well handled by proper use of intravenous fluids and by keeping in mind the fact that this form of shock frequently does not appear for as long as one hour postoperatively. The attendants should be instructed that a slow pulse rate does not mean that all is well but that the appearance of the patient is

extremely important to watch. In all doubtful cases the blood pressure should be taken every half hour. I have frequently seen patients with a pulse rate under 80 and blood pressure at the same time under 70 and even as low as 50. If such conditions are allowed to continue the patient in question would be even more difficult to bring back than the patient with compound fractures and 'crush syndrome' shock in the beds on all sides of him. The anesthetist in the base hospitals seems to be very well handled, but my own feeling is that cyclopropane should be used more often than seems to be routine there.

DR R C MCCARTHY, Toledo Ohio. These methods were presented not as recommendations and not as an ideal setup for a casualty system, but simply as observations of the methods used in England and no doubt they are susceptible to a considerable amount of improvement. They seemed to feel in England though, that the use of spinal anesthesia in fresh cases particularly those showing shock was hazardous, and for that reason it wasn't recommended. The use of intravenous morphine at the first aid posts presents technical difficulties because most of the personnel in these posts aren't physicians, they are not capable of giving intravenous medication and they are supervised by a general practitioner who may not have the opportunity of acquiring proficiency in intravenous technique, especially when done under the circumstances in which he works. There are certain deadly pitfalls to the use of cyclopropane in England. The government there feels that at the present time its use demands special knowledge which the average anesthetist does not have and therefore it is not recommended for routine cases. Moreover the price in England is about three times that in this country and it certainly seems expensive enough here.

ANTICIPATION IN THE INHERITANCE OF DIABETES

R I WOODYATT MD

MARCELL SPETZ MD
CHICAGO

The following lines are in Naunyn's¹ textbook on diabetes.

Very interesting and instructive in its bearing on our conception of the hereditary transmission of the Anlage is the fact that diabetes (in father and sons) can appear earlier in the sons than in the father. I have seen that once. Quite similar cases are reported by Bence Jones, Grube² Niessen³ (1865-1897). Niessen saw a child of 13 years after scarlatina that followed a typhus develop diabetes and die of it a year later. The father a chemist often examined his own urine but found it always sugar free until five years later, when suddenly the disease also appeared in him. The second case of Niessen's is entirely similar.

Extending these earlier observations, Woodyatt⁴ has noted further that when diabetes occurs in three generations of a single family it may appear earlier in the second than in the first and earlier in the third than in the second, the same trend continuing through three generations, also that it can be exhibited to some extent as between older and younger members of a single generation.

When an inheritable character makes its appearance in one generation of a single family at a given age in the following generation at an earlier age and so on the phenomenon is known as anticipation. It is

said to occur in a number of pathologic and teratologic conditions. Davenport and Muncey,⁶ in a study of its occurrence in Huntington's chorea, draw attention to possible sources of error in interpretations of data. However, comparisons of ages of onset of diabetes in different generations of single families leave no room for doubt that the phenomenon occurs in this disease. How often it occurs is another matter. Naunyn's illusion to having seen it only in a single case, and the few reports on this subject that he appears to have been able to find in the literature in 1906 might convey the impression that it was relatively rare. Our own observations have conveyed an opposite impression. It has seemed evident also, from case reports to be found in the literature, that many writers have recorded it although with a few exceptions (cf. Macklin⁷) without commenting on it. Apart from its importance from the point of view of the geneticist, it is also a matter of practical interest in the estimation of the chances that the disease will appear in as yet unaffected members of the families of diabetic persons. As we were not familiar with statistics that serve to settle the question it seemed desirable to collect further data on the subject.

For this purpose we have studied one hundred families in each of which the disease has been known to occur in members of two or more generations and in which the ages of onset could be ascertained. With two or three exceptions the families studied have been those of patients who have come under our care in the Presbyterian Hospital. The ages of onset in the patients have been determined as closely as ordinary clinical methods permit. With the younger patients they are probably exact to within a year. With the older patients there were more chances of error, as the disease could have existed before it was discovered. For the ages of onset in relatives of patients we have depended largely on statements of others which appeared to be substantiated by sufficient evidence to warrant acceptance. When the disease has appeared in two or more members of the same generation the ages of onset have been averaged for that generation. In eighty-eight of the families the disease was observed in two generations, in eleven in three, in one in four. In thirteen of the total there was a history of diabetes on both sides of the family.

RESULTS

In 10 of 100 families studied anticipation was not observed. In 7 of these the reverse occurred, the diabetes appearing later in life in the following generations.

In 90 families the data as recorded showed anticipation in varying degrees. The differences between the ages of onset in two successive generations ran as follows:

No. of Families	Years
5	Less than 5
6	5-10
20	10-20
34	20-30
11	30-50

The differences of less than five years recorded in 5 cases are not beyond limits of possible error in determining actual ages of onset. The differences of five to ten years recorded in 6 others may also fall partly

in the questionable zone. But the differences of ten to fifty years observed in 65 cases are beyond limits of probable or even possible error.

In 10 of 88 families that showed the disease in two generations the diabetes skipped one generation, occurring in the first and third generations. In these families the differences between the ages of onset in the first and third generations varied from twenty-five to sixty-five years.

In 3 of the 11 families that exhibited the disease in three generations it appeared in the first and second, skipped the third and reappeared in the fourth. In 1 of these families (case B-1) a father and son and a father's brother's son all developed the disease at about the same age and at about 45, so that there was no demonstrable anticipation in the second generation. In a numerously represented third generation there is no known diabetes, but a granddaughter of the father's brother's son (a great-grandniece of the first progenitor) has developed the disease at the age of 4. Comparing the ages of onset in the case of the child with that in her grandparent, there is an anticipation of some forty-one years (or of about twenty years per generation of family after the second). In this particular case the diabetes was discovered in the first progenitor in about 1891 and in the great-grand-niece in 1941, so that the trend was not discoverable for some fifty years, which raises the question as to how many of the 10 families of the present series that have failed to show it may do so later. In the other 2 families that showed the disease in the first, second and fourth generations the data are indefinite as to ages of onset in the second generation, but the disease appeared in the fourth generation (the third diabetic generation) at the ages of 3 and 5 respectively, forty and sixty-eight years earlier in life than in the first generation. The trend therefore proceeded at the rates of twenty and thirty-four years per generation. In the 8 families that showed the disease in three successive generations there are also instances in which anticipation was not exhibited in the second generation but was in the third.

In all the families that showed the trend as between two successive generations (either first and second or second and third or both) the average difference between the age of onset in the two generations was twenty years. In all those that showed it as between the first and third or second and fourth the average difference was forty-five years (or twenty-two and a half years per generation of family).

In 20 of the 100 families studied the disease appeared in one or more brothers, sisters or siblings of the patient. In 16 of these the age of onset was earlier in the younger members of these generations. In 6 of the families the situation was mixed, as in a case (M-1) in which the disease appeared in the eldest son of a diabetic father at the age of 5½, in a daughter three years younger at the age of 12, and in a second son ten years younger than the first at 4½. In this case the data are quite exact, because the urines of all the children were tested often at home for sufficient reasons and a difference of six months is probably beyond the limits of error. As between the first and the second son and as between the sister and the second son the trend is definite, but as between the first son and his younger sister the reverse occurred. It so happens that in this case the affected children were the first, third and fourth in a family of four. The second child, a girl a year younger than the first

⁷ Macklin, Madge T. Inherited Anomalies of Metabolism. I. Diabetes Mellitus. J. Heredity 24: 349-356, 1913.

child, is now 17 and not affected. She has passed the ages at which the disease developed in her elder brother, younger sister and younger brother by eleven and a half, five and twelve and a half years respectively. The question is whether she will develop the disease. From the study of the trend in general and in this particular family, the chances of her so doing would seem relatively slight (although the possibility remains, as even identical twins can develop the disease in different periods of life).

COMMENT

Evidence of the trend was definite beyond limits of probable error in determining actual ages of onset in 79, positive but less certain in 85 and suggestive in 90 of 100 families in which the disease occurred in two or more generations. In a number of families that exhibited the disease in three generations the trend was not observed as between the first and the second generation but was observed between the second and the third. As such families would be listed as negative before the appearance of the third generation, and as 88 of the 100 families showed the disease in only two generations, the possibility is suggested that anticipation may be the expression of an inherent potentiality that exists in all cases.

The observations have a bearing on our conception of the course of diabetes and of our understanding of differences in the character of the disease in older and younger subjects. In those families in which the trend appeared, the differences between the ages of onset in two successive generations (or in two with a skipped generation between divided by 2) varied widely in different individual cases, but the general average was twenty years. So in a given typical or composite case (essentially similar to some actual cases) the disease might appear in a first generation in the forties, fifties or later, in a second generation in the twenties, thirties or forties, in a third in the first or second decade. Thus a parent could be affected at the age, let us say, of 50 years, a child of the parent (or nephew or niece) at the age of 30, a grandchild (or sibling) at the age of 10. Or the parent could be affected at the age of 50 and a grandchild at 10 with no diabetes in the second generation. Then a continuance of the trend at the same average rate would bring the age of onset in a fourth generation to minus ten years or to whatever period this may imply in prenatal time. We might think perhaps of nonconception or of the development of the disease in intrauterine life with resultant death of the fetus. In any event, when last seen the trend is pointing in the direction of extinction of the strain (on one side of the family, if not on both).

This gives us the picture of diabetes appearing in a family (that has not exhibited it before so far as we know) and running a definable clinical course but in the family as distinguished from the individual case. The rapidity of the course is measured by the rate of anticipation, which may vary from 0 (or even a minus value) to fifty years or more as from one to the following generation. The whole course can be run in two generations, but it is more commonly completed in three or four and rarely in more. That is to say, we rarely find families with a history of diabetes in more than four generations. In this picture those patients that develop the disease in later life appear as cases of first or second generations. They are offshoots of a vine that has been affected for only a limited time—expressions of a young family diabetes. On the

other hand, juvenile diabetic patients appear as cases of following generations. In families that show rapid anticipation they can be representatives of second generations but with average rates are more often of a third or fourth generation. They are shoots from a vine that has been diseased for a long time—expressions of an old family diabetes. Hence the differences in the average course of diabetes in older and younger subjects.

The foregoing raises the question as to how many of the juvenile diabetic patients encountered in practice (with no history of diabetes in preceding generations) are also in reality similar end results of anticipation. There is much to be said in favor of the view that most or all of them are. In the first place the phenomenon of anticipation can be observed only in those particular families that exhibit the disease in at least two generations. In the general run of hospital cases positive family histories are seldom obtainable in more than 20 per cent and in a third of these the incidence may be in only one generation. So of all families of diabetic patients only a small minority (in our own material less than 10 per cent) could exhibit the phenomenon even if the potentiality existed in all. But in this minority group its incidence is so high as to show that the potentiality must be common if not universal. And when the trend does occur it leads inevitably to the appearance of the disease in early life. So it is logical to infer that many juvenile diabetic patients are produced in this way whether the family history shows it or not. And then the question arises as to whether any of them can be produced in any other way. In this connection there are strong arguments that favor the negative view.

There is no doubt of the inheritability of diabetes, and the evidence is strong at the present time that it is actually inherited (or susceptible of transmission) in every case. It is also obvious that in taking the family history of a child any positive evidence of diabetes in the family, if this exists, must be found either in members of the child's generation or in relatives of preceding generations. It cannot be found in following generations that have not yet appeared. As a matter of fact, the highest percentages of positive family histories of diabetes that have been obtained in any material are those obtained in families of diabetic children, as witness data of Joslin⁸ showing diabetes in the families of 52 per cent of 151 diabetic children who had survived the disease for fifteen years in 1940, and the statement of White⁹ that when these children

were first seen 1 in 5 had a relative with the disease and after fifteen years every other 1 had 2 or more and those of twenty years' duration nearly 3 out of 5. This exceptionally high incidence of diabetes in families of diabetic patients shows that a large proportion of all the children of this series were actually descendants of preceding diabetic generations and the tripling of the incidence in twenty years suggests that more and more cases have appeared or have been discovered, partly perhaps in the same generation but mainly in preceding generations. Surely not more than a negligible part of it could be due to the appearance of the disease in following generations.

The observations are further of some practical interest in connection with estimations of the probabilities that the disease will appear in as yet unaffected relatives.

8 Joslin E. P. in *The Treatment of Diabetes Mellitus*, by Elliott P. Joslin with the cooperation of Howard F. Root, Priscilla White and Alexander Marble, ed. 7, Philadelphia, Lea & Febiger, 1940, p. 47.
9 White, Priscilla, in *The Treatment of Diabetes Mellitus*, p. 671.

of diabetic patients. If the age of onset in a parent should be 40 years, a child of the parent (or nephew or niece) developing the disease would do so, in a large majority of cases, at an earlier age and, on the basis of averages found in this series, at about the age of 10. So if a child should be unaffected at the age of 10 the probability that he would later develop the disease would diminish with every passing year, until at the age of 40 it would become quite remote (although the possibility would still remain that in this particular family the anticipatory trend was not yet in operation). However, if 1 child should develop the disease, the age of onset in his case would afford an index of the critical period for his generation.

In that case a younger brother, sister or cousin of the affected child developing the disease would do so at a somewhat earlier age in a majority of cases (about 4 out of 5 on the basis of averages found in this series). But an older brother, sister or sibling developing the disease would be correspondingly more likely to do so at a somewhat later age. In their cases the chances of being affected would diminish only after they had passed the critical period for their generation. In a majority of cases the ages of onset in different representatives of the same generation of a given family fall within a span of ten to fifteen years (with notable exceptions in a minority group). Of pertinence here are data on variations of ages of onset in 2 affected members of pairs of twins. In Priscilla White's series of 48 cases of diabetes in twins there were 14 cases in which the disease occurred in both members of the pair. In 11 of these, or about 80 per cent, the ages of onset were 2-3, 5-8, 3-13, 9-12, 17-29, 47-52, 55-53, 56-63, 57-57, 60-62, 62-62 (greatest spread twelve years). The other 3 cases (20 per cent) showed greater variations, e. g. 35-60, 29-67, 19-67 (greatest spread forty-eight years). While we have no data on a long series of cases to show the exact proportion of families in which the ages of onset in one generation fall within a span of ten to fifteen years, our impression would be that the foregoing is a fair index of the general run.

The same principles that apply to the brothers, sisters or siblings of the child in question would also apply to older and younger brothers or sisters of the parent. Again, if diabetes appears in a child (of a family that has not exhibited the disease before) it may develop later in members of preceding generations. The probability that it will appear in the generation of the parent does not lessen until after the passage of ages twenty years greater than the age of onset in the child, and then but gradually for another decade. Again, if a parent developed the disease at 50 to 60, a grandchild who developed the disease at all would be more likely to do so in the first or second decade of life, and so on. It is hardly necessary to say that in estimating the chances of a given relative of a diabetic patient other factors besides anticipation require consideration, such as possible mendelian ratios, but that knowledge of the former is an added help.

In accordance with the view that diabetes is transmitted on mendelian lines as a recessive trait, if a father and mother are both diabetic (or potentially so) 100 per cent of the children should develop the disease if they live long enough, or if one parent is diabetic and the other a carrier, 50 per cent, if both are carriers, 25 per cent, if one is a carrier and the other normal, 0 per cent, but then all the children would be carriers capable of transmitting the disease. In this

connection the foregoing discussion of anticipation raises the question as to the chances that a juvenile diabetic patient would run of producing a living child that would develop diabetes after birth. If the partner is also a juvenile diabetic patient it might seem that the probability would be most remote. If the partner is diabetic (or potentially diabetic) but of a first or second generation of his or her family, the situation might differ, as a child conceivably could represent a later generation of the partner's family. The question can be settled only with the accumulation of data on the incidence of the disease in progeny of persons who have had diabetes in childhood.

IMPROVED LOCALIZATION AND TREATMENT OF RUPTURED INTERVERTEBRAL DISKS

WALTER E. DANDY, M.D.
BALTIMORE

My purpose in this communication is twofold to suggest (1) a method of localization of ruptured intervertebral disks and (2) an improved method of operative attack on the disks.

In previous communications I have emphasized the ease with which the diagnosis of a ruptured disk can be made solely from the patient's story of low backache plus sciatica, occurring in attacks, usually after a relatively trivial injury such as a lift, bend or strain. During the acute stages the pain in the back and the sciatica are usually intensified by coughing and sneezing. Although there may be sensory and motor loss from local pressure on the nerve, the only really valuable objective finding is a diminution or loss of an achilles reflex, and this occurs in only about half of the cases. The subjective story is therefore all important, and negative objective findings are of no concern. Moreover, this is one of the most common lesions in the field of surgery. In industrial work these patients are passed along as having neuroses. Since the diagnosis can be made with almost absolute accuracy by the clinical symptoms alone, lumbar punctures, injection of contrast mediums such as air, iodized poppyseed oil and thorotrast into the spine are entirely unnecessary. They are in fact strongly contraindicated, for the small disks do not show with any contrast mediums and if dependence is placed on their findings the patient is denied the operative treatment that provides the only cure. In the last 350 operations for ruptured disks I have failed to find the disk only once, a spinal cord tumor being the causative lesion.

In a recent publication the small so-called concealed disks were described. Clinically the signs and symptoms are precisely like the protruding disks and the treatment is the same. All of these would be missed by intraspinal injections of contrast mediums and they now outnumber the protruding disks 3 to 2. It is the failure to detect the concealed disks at operation that has cast so much discredit on this field, which is really one of almost absolute precision. They are less obtrusive at operation, but with a surgeon who is skilled in this type of operation their recognition is just as unequivocal as the larger ones. The difference in recognition is not unlike that of differentiating a small from a large carcinoma of the breast to the expert one is just as definite as the other. There are only

three or four other lesions that can give symptoms fairly similar to a disk, i. e. backache and sciatica (in attacks) (1) tumors of the cauda equina, (2) congenitally defective fifth lumbar vertebra with destruction of the articular processes and (3) spondylolisthesis. All of these are relatively uncommon. The latter two can be differentiated by the x-ray plates. Spinal tumors will usually give some sensory or motor disturbances in addition, but they may not. However, the percentage of error from this source is so low (1/500 in my experience) that iodized oil injections to exclude them would be unwise.

Perhaps a fourth possibility of error should be mentioned—carcinoma invading the low retroperitoneal spaces. Here the pain does not occur in intermittent attacks and is not intensified by coughing and sneezing.

One of the most important contributions to this field has been the statistical studies of Love and Walsh and of Spurling and Grantham, both publications appearing in the same journal (*Archives of Surgery* 1940). Their observations came to the same conclusion: that 96 per cent of all ruptured disks were in the lumbar region and 98 per cent of the lumbar disks were at the fourth and fifth. My studies entirely confirm their conclusion. Occasional disks are encountered at the second or third lumbar interspaces but the symptoms are sufficiently different (usually pain in the front of the leg or diminution of the patellar reflex) to suspect the lesion higher than the routine levels. In these cases iodized oil may be advisable for the exact determination of the level, although I now feel that the test as described is adequate to make this determination.

With the standard pain in the lower lumbar region and down the hip and back of one or both legs the affected disk is therefore nearly always at lumbar 4 or 5, and it has been necessary to explore only one or both of these disks to find it. Frequently the exploration of one interspace would disclose the disk but at other times it would be necessary to explore the second when the first was negative. Frequently there is a lead, such as a reduced or absent achilles reflex which points to the fifth, although it may also exist with one at the fourth. Also a narrowed disk may be evident in the roentgenogram. As a matter of fact the exploration of two interspaces is a minor matter since Love introduced his successful operative technique of exposing and removing many disks without sacrificing any bone. The disks can usually be explored after removing only the ligamentum flavum. At most only a bite of a lamina is necessary.

LOCALIZATION TEST

The following test provides greater precision in locating the disk without exploring it. When the unilateral exposure of the spine has been made the cutaneous incision is perhaps 4 inches long and uncovers both the fourth and fifth laminae. A periosteal elevator pushes the spines of the fourth and fifth spinous processes downward, i. e. caudally, and determines the mobility of each vertebra. The disk will be where the greater movement is shown. This test is effective because the defective disk has weakened the spinal column locally and this in turn causes mobility. It is this free play at the disk that is responsible for the intensification of the pain by coughing and sneezing. If the patient can stiffen the back before the cough or sneeze, the pain will be ameliorated. If the third disk is suspected, the same free play of the spine can be elicited there and in a recent case was

the means of establishing the site of the affected disk when there was another at the fourth. In 10 cases it has made possible the diagnosis of two disks—one at the fourth and the other at the fifth—a not uncommon finding. A corollary to this observation is also interesting. In 6 cases during the past year reexploration of the wound for recurring symptoms has shown that the site of the previous mobile disk from which a ruptured disk had been removed was then firm and free of movement three to six months later. In each instance the second disk was responsible for the symptoms. This test of spinal mobility is not absolute occasionally the degree of mobility is not decisive, and at times a disk will heal and solidify the vertebrae, leaving the extruded cartilage encapsulated under and attached to the nerve. However in over 85 per cent of the cases it will correctly determine the site of the lesion.

OPERATIVE TREATMENT

Hitherto the operative treatment of ruptured disks by most surgeons has been to remove protruding cartilage and as much as can be pulled out of the depths of the necrotic interior of this disk. However I have always insisted that the interior of the disk must be treated by breaking up the contents with the forceps. Otherwise recurrence will occur in a considerable percentage of cases. For the concealed disks in which but little cartilage can be extracted the interior of the disk has been broken up with forceps. The eventual cure has depended therefore, on the subsequent extrusion of the necrotic contents through the opening. With few exceptions this treatment will effect a cure but not infrequently the period of convalescence will be protracted over a period of two or three months.

In only 1 instance has there been an actual recurrence of the disk. However in 5 cases in this series I have reopened the wound expecting a recurrence but in each instance there was only the unhealed cavity in the disk doubtless because the necrotic contents remained more or less attached and had not yet been extruded. These too must be considered recurrences. Two thoughts developed from these cases: (1) that a thorough removal of the necrotic contents would hasten the postoperative period of recovery and (2) that it was probably better to remove enough of the living cartilage to bare the bone and permit granulations to fill the cavity. Since the introduction of this procedure three months ago the recovery has been consistently inevitable and it has not been necessary to reopen a wound. This applied to both the concealed and the protruding disks. It must be realized that in all cases the entire center and much of the periphery of the disks are destroyed. After the ligament covering the disk has been widely opened the edges are cut downward with a narrow sharp periosteal elevator and the whole interior of the disk is thoroughly curetted and as much as possible removed. Many small and even large pieces of cartilage can be extruded after this debridement.

CONCERNING FUSION OPERATIONS

There are many surgeons—and I think an increasing numbers—who advise fusion (grait) operations on the spine to stabilize it afterward. When one considers the mobility induced by the defective disk this is perhaps not an illogical assumption. But when one sees the firm union that eventually results after the disk has healed with fibrous tissue it is clear that a fusion

is entirely unnecessary. I therefore feel very strongly that fusion operations are inadvisable and unnecessary. Following a fusion operation the patient must be immobilized in a cast for approximately two months—a severe hardship and one that is unnecessary.

There are times when a congenitally defective fifth vertebra with or without spondylolisthesis, may closely simulate a disk or may be associated with a disk. These patients are prepared for a possible fusion. If there is a defective disk the fusion is not done. If there is no concomitant disk the fusion is in order.

A word is perhaps in order about the abuse of fusion operations. All too frequently patients are fused with or without search for an offending disk. After prolonged hospitalization the graft has accomplished little or nothing in relieving the patient's symptoms; removal of the graft and treatment of the disk must subsequently be done. A possible need for the fusion operation is based entirely on the x-ray findings, i.e., spondylolisthesis or a defective fifth lumbar vertebra. And with either of these conditions a defective disk may or may not be present. With such findings preparation for a fusion is made at the time of the operation and is carried out only when there is no disk. The orthopedic staff works in close affiliation with me in this problem, and in 4 such cases a fusion has been done. In 6 cases in which a doubt was entertained a disk was found and the fusion operation avoided. This is an important decision and all depends on the operator's skill in detecting defective disks. And again, it should be emphasized that the concealed disks can easily be missed and with tragic results.

WHEN IS OPERATIVE TREATMENT FOR DEFECTIVE DISKS ADVISED?

In the final analysis the answer to this question is the amount of pain the patient suffers. Spontaneous cures of ruptured disks must be very uncommon. Remissions in symptoms are the rule, but throughout life the patient is subject to repeated attacks following slight strains on the spinal column—such as lifting, bending, twisting or slipping. This is one of the most common ailments and one of the most debilitating, one of the easiest to diagnose and to cure permanently and with no risk. Why then delay treatment? Moreover, there are very few sciaticas with low backache that are not due to defective disks. I feel very strongly that when a patient has enough pain to consult a physician he should be operated on. Without operation one's activities can continue only at a reduced pace and with the ever present dread of recurring attacks. In the acute attack, whether the first or subsequent ones, the pain, which is so often excruciating, can be stopped at once by the operation. Delay only means more suffering and subsequent attacks.

SUMMARY

The foregoing additions leave little to be added subsequently in making the diagnosis and treatment of defective lumbar intervertebral disks almost free of error, and with almost perfect results. Recurrence of a disk should be very rare when it has been properly treated. The diagnosis and localization of the affected disk are nearly absolute on the clinical story alone. Lumbar punctures and intraspinal injections of contrast mediums are unnecessary, and if dependence is placed on them findings the chances of correct diagnosis are greatly lessened.

A low backache plus sciatica down the back of the leg, intensified by coughing and sneezing are almost pathognomonic of a defective lumbar disk. The operative treatment is absolutely safe and a cure is practically assured.

Clinical Notes, Suggestions and New Instruments

PNEUMOCOCCUS (TYPE XXVIII) ENDOCARDITIS WITH RECOVERY

NATHAN BLUMBERG, M.D., WILLIAM I. HEINE, M.D., AND JACK LIPSHUTZ, M.D., PHILADELPHIA

Recovery from pneumococcic endocarditis is rare. We have been able to find only 2 previous reports of its occurrence. Preble¹ in 1904 reported 2 cases, 1 of which can be interpreted as pneumococcic bacteremia associated with lobar pneumonia occurring in a patient with antecedent rheumatic heart disease. His other case appears more genuine. A girl aged 18 years had severe chills and fever five days after recovery from pneumonia. Systolic and diastolic murmurs were then heard; the heart having previously been normal. Pneumococci were found on repeated blood smears and cultures. The temperature returned to normal after being elevated for six days and the patient made a clinical recovery. The murmurs persisted. Embolic phenomena were not noted.

Laubry and Coffin² reported 1 case. A woman aged 56 had a prolonged febrile course and during the course of her illness a systolic mitral murmur developed. Two blood cultures showed growths of pneumococcus type II. A later culture however revealed paratyphoid B. There were no embolic phenomena. Recovery occurred after a protracted course. Therapy included the use of antipneumococcus serum.

REPORT OF CASE

History.—G. K., a youth aged 18, admitted to the medical wards of the Jewish Hospital Dec. 18, 1941, complained of chills, fever, sweats and malaise of three weeks duration. The patient had been well until Nov. 25, 1941, when while at work as a painter, he noted chilliness, generalized aches and pains, malaise and sore throat. During the next few days he had severe chills followed by drenching sweats and high fever.

About two weeks before the onset of his present illness the patient had noted an abscess in his left upper gum. One week later the abscess ruptured spontaneously and discharged purulent material. The site remained slightly tender thereafter. There had been no active manipulation of the abscess or the teeth.

In the past history it was noted that a left otitis media had occurred seven years previously. In November 1940 he was admitted to another hospital for an injury to his left eye. At that time his heart was normal in size and no murmurs were heard. There was no history of rheumatic fever, scarlet fever, chorea, tonsillitis, epistaxis or joint or growing pains. The family history was not significant. The patient had been employed as a painter for the past two years.

On Dec. 1, 1941, he was seen for the first time by one of us during a severe chill. The only positive conditions on physical examination were a loud harsh blowing systolic murmur at the apex of the heart transmitted to the axilla and injection of the pharynx and tonsillar area with a few patches of white exudate of each tonsil. No medication was given during the next few days. Chills and fever occurred daily. The patient complained of generalized aches and pains. There was no evidence of any joint involvement. On December 4 the administration of sulfathiazole (1 Gm. four times a day) was

From the Medical Service of the Jewish Hospital.

2. Laubry, C. and Coffin, M. Primary Infectious Pneumococcic Endocarditis Terminating in Recovery. *Bull. et mem. Soc. med. d. hop. de Paris* 52: 281, 1928.

instituted with little effect on the patient's clinical signs or symptoms. On December 10, sulfadiazine (1 Gm four times a day) was begun. On December 13 the patient complained of pain in the calf of the right leg. Examination at that time revealed only tenderness of the right calf. There was no discoloration, swelling or limitation of motion and no alteration of pulses in the extremity. The injection of the throat gradually subsided, the exudate disappearing. The murmur previously described persisted. Because of the persistence of the chills, fever and sweats, the intensity of the murmur and the possible embolism to his right leg, the patient was hospitalized with a tentative diagnosis of bacterial endocarditis.

Examination—The patient was thin and on admission to the hospital did not appear in acute distress. His temperature was 99.8 F, the pulse rate 100 a minute and the respiratory rate 20 a minute. There was no dyspnea, cyanosis, jaundice or lymphadenopathy. No petechiae were visible. There was a scar on the left cornea extending from 10 o'clock on the limbus to the center with anterior synechia. The fundi were normal.

The tonsils were not enlarged and the pharynx was slightly injected. The oral hygiene was poor. Several teeth were missing and several others contained cavities. On the gum above the left lateral upper incisor was a small white spot which was slightly tender but from which nothing could be

Patient's course in the hospital

expressed. The chest was clear. The heart was not enlarged and no thrill was felt. The rhythm was regular, the sounds being of good quality. A loud, rasping systolic murmur was heard at the apex and was transmitted toward the axilla. The second sound at the pulmonary area was accentuated and split. The blood pressure was 110 mm of mercury systolic and 70 mm of mercury diastolic.

The liver and spleen were not palpable. There was no tenderness of the costovertebral angle. Rectal examination was negative. There was no edema of the extremities. Pulsations in the dorsalis pedis and posterior tibial arteries were good and equal on the two sides. There was slight tenderness in the calf of the right leg. Neurologic examination was negative.

Course—The course in the hospital is shown graphically in the chart. The day after admission the patient felt fairly well, his temperature reaching only 101.4 F. Laboratory studies revealed a normal urine, blood sugar, blood urea nitrogen and a negative Wassermann reaction of the blood. The blood count was hemoglobin (Sahli) 12.8 Gm per hundred cubic centimeters (93 per cent), erythrocytes 4,600,000 per cubic millimeter and leukocytes 18,500 per cubic millimeter, with a differential count of 87 per cent neutrophils and 13 per cent lymphocytes. The blood sulfadiazine level was 272 mg per hundred cubic centimeters. The blood sedimentation rate (Cutler) was 26 mm in one hour. An electrocardiogram was normal. By roentgen examination the heart shadow and lung fields were normal.

On December 20 and once or twice daily thereafter for about ten days, the patient experienced severe shaking chills

following which his temperature would rise to a peak of 102 to 106 F. He would then perspire profusely, with a concomitant fall in temperature. Blood cultures taken before and during the chills showed no growth.

On December 24 the patient complained of headache and a stiff neck. Nuchal rigidity was present and a positive Kernig sign was elicited. Examination of the ears, nose and throat was negative. No focal neurologic signs were present. Otherwise the examination was as noted on admission. Lumbar puncture revealed a cloudy spinal fluid under a pressure of 190 mm of water. The fluid contained 18,000 leukocytes per cubic millimeter with a differential count of 95 per cent polymorphonuclears and 5 per cent lymphocytes. The chlorides were 700 mg per hundred cubic centimeters, Fehling's solution was not reduced and the protein was 250 mg per hundred cubic centimeters. No organisms were seen on smear and there was no growth on culture. Sulfadiazine was then given by mouth, 10 Gm on December 24 and then 1 Gm every four hours day and night. The symptoms and signs of the meningitis cleared rapidly during the next few days but the chills and fever persisted. The blood sulfadiazine concentration was maintained at about 10 mg per hundred cubic centimeters. On December 26 the spinal fluid contained 900 cells per cubic millimeter with 80 per cent polymorphonuclears and 20 per cent lymphocytes. The chlorides were 650 mg, the sugar was 85 mg, and the proteins were 30 mg per hundred cubic centimeters. The sulfadiazine level in the spinal fluid was 5 mg. A smear showed no organisms and cultures were again sterile.

On December 27 the patient complained of sudden pain in the upper inner portion of the right arm and of numbness and coldness of the right forearm and hand. On examination the right forearm and hand were cold and mottled blue. There was tenderness in the upper inner portion of the right arm. No pulsation was felt in either the right radial or the brachial artery. A faint pulsation was felt in the right axillary artery.

With the oscillogram very slight oscillations of the needle were noted in the right upper extremity with normal oscillations on the left. Papaverine hydrochloride was administered in doses of 1/2 gram (0.032 Gm), at first intravenously and then orally. Also the affected extremity was wrapped in lamb's wool and placed in a heat cradle. Following the institution of these measures, the pain diminished and the color and temperature improved.

The following morning, December 28, the patient complained of sudden pain in the calf of the left leg. The left foot was cold and blanched and there was tenderness in the upper portion of the calf. No pulsation could be felt in the left posterior tibial, dorsalis pedis or popliteal artery but there was good pulsation in the femoral artery. Oscillogram readings were zero below the knee, normal above. A paravertebral block with procaine hydrochloride at the level of the first, second and third lumbar vertebrae on the left was instituted, papaverine hydrochloride continued and heat applied.

On January 1, 1942 reappearance of pulsations was noted in the right brachial and radial arteries and the left posterior tibial artery. The pulsations gradually increased in strength but the difference from those in the unaffected extremity could easily be detected.

The patient's temperature continued to range between 98 and 101 F. Subjectively he felt well. The heart remained normal in size and the murmur changed slightly with variations in the heart rate, but otherwise it was constant. No petechiae were noted. The spleen was not palpable. The leukocyte count remained about 10,000 per cubic millimeter. The erythrocytes gradually fell to 3,100,000 per cubic millimeter. Blood cultures, both aerobic and anaerobic, persistently failed to show growth even though observed up to sixteen days. Para-aminobenzoic acid was added to the mediums when the patient was receiving the sulfonamides. On January 5 the spinal fluid was clear, under normal pressure and contained no cells. The sulfadiazine concentration on that day was 4.6 mg in the spinal fluid and 7 mg in the blood. On January 5 and 7 the urine contained many red blood cells and on the latter date many crystals of sulfadiazine also. On January 8 the sulfadiazine was stopped, a total of 97 Gm having been administered in the hospital.

The patient's temperature then gradually rose and on January 14 reached 103 F. The next day sulfathiazole was started with a dose of 2 Gm and then 1 Gm every four hours. His condition remained essentially unchanged, except for some lessening of his fever, until January 28 when a right hemiplegia suddenly developed involving the face and upper and lower extremities. There was a pronounced motor aphasia but consciousness was not lost. The next day, January 29 the blood culture taken on January 23 was reported as showing a growth of pneumococcus type XXVIII. The blood culture taken on January 24 was subsequently reported to show a growth of the same organism. Twenty cc of blood was taken for each of these cultures ten minutes after the subcutaneous administration of 3 minims (0.2 cc.) of epinephrine. On smear of the colonies the organisms were gram-positive encapsulated diplococci. The cultures were bile soluble and on milk produced both acid and a coagulum. Mice were readily killed after intraperitoneal injection of the cultures. The organisms in the peritoneal washings gave a prompt quelling reaction with type XXVIII pneumococcus serum.

On February 3 the peak of the patient's temperature was below 100 F and after February 8 never rose above 99.4. Sulfathiazole 1 Gm every four hours was continued. Between February 6 and 13, 540,000 units of type XXVIII antipneumococcus rabbit serum was administered intravenously (100,000 units each on February 6 and 7, 40,000 units on February 9 and 100,000 units each on February 11, 12 and 13). Intra-dermal and ophthalmic sensitivity tests were negative and the patient had very little reaction except for a moderately severe chill after the first dose. After February 6 the leukocyte count remained under 10,000 per cubic millimeter. The erythrocyte count gradually rose. The sedimentation rate, however, continued persistently rapid. The patient's murmur remained constant. He was alert although the aphasia persisted to a strong degree. Heat and massage were administered to the paralyzed limbs. He regained fair motion of the right lower extremity but very little of the right upper extremity. Spastic hyperactive reflexes and pathologic reflexes persisted in both.

On March 13 his leukocyte count was 7,000 per cubic millimeter and his erythrocyte count 4,300,000. Urinalyses were repeatedly negative. The blood sulfathiazole level had been maintained between 4 and 6 mg per hundred cubic centimeters. Twenty blood cultures taken subsequent to the positive ones were all sterile.

On March 14, three months after admission the patient was discharged from the hospital with a diagnosis of type XXVIII pneumococcus endocarditis with emboli to the meninges, right brachial artery, left popliteal artery and left middle cerebral artery.

Subsequent Course—Since discharge the patient has shown gradual but steady improvement. Sulfathiazole was continued in gradually decreasing doses and was stopped on April 21. He is able to walk but the leg is still somewhat spastic. There has been a slight improvement in the right arm. The aphasia is gradually diminishing. The murmur is still easily audible but appears not quite so rough or loud. There have been no further embolic phenomena. Pulsations in the vessels of the right arm and left leg are still noticeably diminished. His temperature, pulse rate, blood count, urinalysis and sedimentation rate are all normal. Several more blood cultures taken since his discharge have been sterile. The patient feels well and at present is attending a special school where reeducation is being attempted.

COMMENT

We feel that a diagnosis of type XXVIII pneumococcus endocarditis is justifiable on the following grounds: (1) the absence of a history of previous heart disease and the normal cardiac findings in another hospital a year prior to the onset of his present illness, (2) the septic course, (3) the type of murmur, (4) the embolic phenomena and (5) the recovery of type XXVIII pneumococci in two separate blood cultures.

The origin of the pneumococci is obscure; that the patient did not have pneumonia is definite. Other possibilities are the fistula over the left lateral upper incisor and the infected tonsils and pharynx.

We believe that recovery has occurred on the basis of (1) the return to normal of the temperature, leukocyte and erythrocyte counts, (2) the absence of further embolic phenomena, (3) the persistently negative blood cultures and (4) the pronounced improvement in the patient's general condition.

The relationship to recovery of the therapeutic agents employed is open to question. During the administration of sulfadiazine there was diminution in the chills and fever, which however recurred when the drug was discontinued. The embolic phenomena and the positive blood cultures were obtained during active treatment with sulfathiazole. Concomitant with the administration of type-specific rabbit antipneumococcus serum in addition to the sulfathiazole, the temperature declined and recovery ensued. Whether the serum was instrumental in bringing about recovery or whether the administration was coincidental to spontaneous recovery is a moot point.

HANDBOOK OF NUTRITION IX

THE TRACE ELEMENTS IN NUTRITION

MAURICE E. SHILS, ScD

AND

E. V. McCOLLUM, PhD, ScD

BALTIMORE

These special articles on foods and nutrition have been prepared under the auspices of the Council on Foods and Nutrition. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the Council. These articles will be published later as a Handbook of Nutrition.—Ed.

The many mineral elements which exist in animal tissues occur in widely varying amounts. They range from calcium, which comprises approximately 2 per cent of the adult human body weight and which can be expressed in kilograms, down to those which we must measure in milligrams and even micrograms, and which have been termed "trace elements." The dividing line between trace and non-trace elements is purely arbitrary and a matter of choice. Some nutritionists¹ include in the former category any element occurring in the tissues or nutritionally necessary in amounts equal to and less than iron, but others² consider only those elements below iron.

Presaging the point of view that traces of minerals might exert profound and specialized physiologic effects were the discoveries that iodine occurs in the thyroid,³ copper in octopus blood⁴ and in the hemocyanin of crustacea,⁵ zinc in the hemoscotopin of oysters,⁶ vanadium in the blood pigment of the sea squirt⁷ and

manganese in the blood of the mollusk *Pinna squamosa*.⁸ Nevertheless, with the exceptions of iron and iodine little physiologic significance was attached to the others of the trace elements until comparatively recently. Beginning with the investigations on their distribution, especially those of Bertrand in France, the importance of the trace elements has come to be realized primarily through the study of experimental animals on purified diets and through the work on diseases of live stock.

The importance of iron, copper and iodine, the trace elements first demonstrated to be essential has been discussed in previous papers. Knowledge of the mode of action of these three elements and of those discussed here indicates that the role of "traces" is one of participation in the activities of hormones and enzymes, a role, in all probability, analogous to that of the vitamins. These elements are of importance nutritionally because optimum physiologic activity requires certain of them at least in proper amounts. Biologic relationships are such that lack of the essential "traces" results in deficiency symptoms while excesses result in toxic symptoms.

To date at least twenty trace elements other than iron, copper and iodine have been reported to occur, many not consistently in animal tissues and milk.⁹ We shall discuss the elements which we consider of principal nutritional interest at this time, namely manganese, cobalt, zinc, fluorine, selenium, boron and aluminum.

MANGANESE

Conclusive evidence for the essential nature of manganese for animals was first demonstrated in 1931.¹⁰ Although earlier investigators¹¹ claimed that they had shown this fact their results were not conclusive.

Orent and McCollum¹ found that mice reared from weaning on a diet adequate except for manganese developed sterility and testicular degeneration after ninety days. Females on the same diet delivered young which survived but a short while, in addition they failed to suckle normal stock young. Hemoglobin regeneration, estrus and growth were not affected by the deficiency.

When mice were reared on a manganese low diet consisting of whole milk supplemented with iron and copper, decreased growth and an abnormal estrus cycle resulted.¹²

Daniels and Everson¹¹ fed a manganese deficient mineralized milk diet to rats and confirmed the fact that the females produced nonviable young. However, their findings differed from those of Orent and McCollum¹² in that the deficient females suckled normal foster young.

Recently we¹³ found that manganese is essential for the normal growth of the rat. The symptoms of deficiency in the female's production of nonviable young can be cured as well as prevented by manganese. In accord with the findings of Daniels and Everson¹¹ the deficient females, while losing their own young, could suckle normal foster young. The few young which did survive to weaning uniformly showed weakness and incoordination most pronounced in the third week of life, with poor growth and poor equilibration persisting throughout life. Manganese is needed for the proper development of other functions in addition to the reproductive. Boyer and co-workers¹⁴ have likewise found that manganese is essential for growth in the rat. Using a mineralized milk diet they observed the symptoms obtained in mice on a similar diet¹² and in addition a marked delay in the opening of the vaginal orifice.

The differing findings of the Hopkins and Wisconsin workers on the reproductive ability of the deficient rats and mice is probably explained on the basis of differences in the magnesium content of the diets used. Purified diets have not yet been brought as low as whole milk in magnesium content. If this is true, then different symptoms occur at different levels of intake. It is possible that unknown dietary relationships might also have caused the differences.

The species differences in deficiency symptoms and requirement of which we are well aware in the case of the vitamins, extends to the trace elements. Investigations of manganese deficiency in chickens have resulted in knowledge of practical importance. The requirements of this species are much higher than those of any mammal studied and the most manifest symptoms are different. Manganese has been shown¹⁵ to prevent the development of an osteodystrophy of chickens called perosis. The symptoms are enlargement of the tibial-metatarsal joint, twisting and bending of the distal end of the tibia and of the proximal end of the tarsometatarsus and slipping of the gastrocnemius tendon from its condyles, resulting in severe crippling. The deficient chicks have shortened leg bones¹ and vertebral columns.¹⁶

It has long been known that excess calcium and phosphorus in the diet intensify perosis and that injected manganese is more efficiently utilized than that given orally. *In vitro* and *in vivo* experiments¹⁷ have helped explain these observations by showing that manganese

is removed from solution by insoluble calcium phosphate or by ferric hydroxide and so rendered unavailable

The chick embryo, like that of the rat, requires manganese for normal development. Lyons and Insko²⁰ observed a very low hatchability of eggs of deficient hens; the embryos which developed sufficiently were chondrodystrophic and the few which hatched also had shortened leg and wing bones (micromelia). Injection of manganese into the eggs prior to incubation resulted in normal development. Caskey and Norris²¹ have observed in ataxia accompanying the micromelia.

The fact that only slight differences in manganese content are found between the decidedly different bones^{1,2} and egg shells - of normal and manganese deficient chickens is indication that probably manganese plays some indirect or catalytic role in calcium and phosphorus metabolism. The possibility of manganese deficiency as a factor in producing bone abnormality in rats³ and lameness in pigs⁴ has been pointed out.

The specificity of manganese as the inorganic factor preventing perosis has been demonstrated. However, the discovery that deficiencies of choline⁵ and of biotin^{6a} result in perosis in fowl is an indication that there are other factors necessary to prevent abnormal bone metabolism resulting in perosis. Periotic malformation may occur as a result of stress and strain on the retarded and abnormal bones of the deficient animal.^{6b} It is suggested^{6b} that the symptoms of "slipped epiphyses" in children^{7a} resemble those of perosis. Biochemical and histologic comparisons of these bone abnormalities would be of interest.

A relationship between manganese and thiamine has been postulated.⁷ Large amounts of thiamine or manganese given to rats caused reproduction and lactation failures which could be prevented by increasing the intake of the other of the two substances.⁸ In addition, rats on a thiamine low diet receiving excess manganese were more quickly depleted than those not receiving it.⁹ The implications of the work merit its being repeated.

That the need for manganese is widespread is indicated by the fact that in addition to the animal species

already discussed, it has been found essential for plants,³⁰ including fungi³¹ and several bacteria.³²

There is no definite information about the human requirements for manganese nor is there evidence of deficiency ever occurring in man. Everson and Daniels,³³ on the basis of balance studies, suggest that the diet of preschool age children should contain between 0.20 and 0.30 mg of manganese per kilogram of body weight, retention in children 8 to 12 years of age was only 0.02 ± 0.22 mg daily.³⁴ Approximately 4 mg is found in the daily adult human diet³⁵ and substantially equivalent amounts are excreted. The manganese content of various foods has been determined, and it is apparent that plant foodstuffs are the chief source in the diet.³⁶ It occurs regularly in the tissues of animals, with liver containing the greatest amount.³⁷ There is a great rise in the percentage of manganese in the human fetal liver during the last months of pregnancy.³⁸

After oral, subcutaneous or intraperitoneal administration, manganese is excreted almost entirely in the feces with only small amounts being excreted in the urine.³⁹

After the necessity for copper as a complement to iron in hemoglobin formation had been established,⁴⁰ a controversy arose as to whether certain other elements could replace copper in this important function. Some investigators⁴¹ have claimed that manganese could, but today the evidence to the contrary is quite conclusive.⁴²

Acute and chronic manganese poisoning in man and experimental animals has been reviewed.⁴³

Manganese and Enzyme Activity—Since Bertrand in 1897 first implicated manganese⁴⁴ (erroneously, as we now know⁴⁵) as the activator of the oxidase laccase,

this element has been found to activate a number of enzymes

Of particular interest is the observation of Wiese and his co-workers⁴⁶ that manganese deficient chicks with perosis have a lower blood and bone phosphatase activity than normal birds and that the decrease in phosphatase activity precedes the appearance of perotic symptoms. This decreased activity may be due not only to decreased manganese concentration but also to an actual decrease in the amount of enzyme present.⁴⁷

In *in vitro* experiments manganese has been found to activate not only blood and bone phosphatases⁴⁷ but also the phosphatases in liver,⁴⁸ yeast,⁴⁹ intestine and kidney⁵⁰ and, although other divalent ions (magnesium, cobalt and iron) also activate phosphatases, they are not as effective in most cases as manganese.

Another enzyme with which manganese has been implicated is arginase, which is accepted as playing an important role in the formation of urea.⁵¹ The strong activating effect of manganese on this enzyme led Edlbacher and Pinosch⁵² to postulate that it is a protein-manganese complex. Richards and Hellerman⁵³ have given more definite evidence for the possibility that manganese is the physiologic activating ion, although cobalt and nickel can produce high activity *in vitro*. The evidence for the *in vivo* activity of manganese has been strengthened by the demonstration of a decrease in the arginase activity of manganese deficient rats.^{53a}

Among the other enzymes whose activity increases with the addition of manganoous ions are (a) phosphoglucomutase⁵⁴ (which causes a transfer of phosphate from carbon atom 1 of glucose-1-phosphate to carbon atom 6 in carbohydrate metabolism), (b) intestinal peptidases,⁵⁵ (c) cholinesterase,⁵⁶ (d) cozymase,⁵⁷ (e) isocitric dehydrogenase⁵⁸ (which catalyzes the reaction isocitric acid to a ketoglutaric acid) and (f) yeast and animal carboxylase,⁵⁹ which contain diphosphothiamine. In yeast carboxylase, magnesium appears to be the naturally occurring activating ion, but *in vitro* manganese can quantitatively replace it. (g) The

adenosinetriphosphatase activity of the muscle protein, myosin^{59a} has been found to be activated strongly by calcium and manganese.^{59b} All the enzymes listed are activated *in vitro* by one or more divalent ions in addition to manganese. The determination of the naturally activating metallic ion or ions and the manner of their action may be of value.

Rudra⁶⁰ has found the presence of manganese necessary for the *in vitro* and *in vivo* synthesis of a reducing substance, presumably ascorbic acid, by rats and guinea pigs and their tissues. As yet there are no reports of scorbutic symptoms in animals on manganese low diets.⁶¹ Furthermore, it has been found that in manganese deficiency in the rat there is no lowering of the ascorbic acid content of various tissues,^{1,2} Rudra's findings were not substantiated.^{1a}

COBALT

Our present knowledge of cobalt indicates that it is essential for at least several animal species and occurs in both plant and animal tissues in very small amounts.⁶² Its distribution in animal tissues has been recently determined again by the use of the radioactive form⁶⁴ and confirmatory evidence obtained that it occurs in highest concentrations in glandular organs, especially the pancreas, liver, spleen and kidneys. Absorbed or injected cobalt, unlike manganese, is excreted in the urine, but the greater part of ingested cobalt is not absorbed.⁶⁵

Bertrand,⁶⁶ on finding that the pancreas is relatively high in cobalt and nickel, suggested that these metals might be connected with the synthesis of insulin. He claimed a prolongation of insulin hypoglycemia on injection of cobalt; nickel had less effect. This effect of cobalt has not been confirmed.⁶⁷ Nickel has more recently been found to delay insulin hypoglycemia.⁶⁸ However, a number of metal salts have been found to influence the onset and extent of insulin hypoglycemia, notably zinc, so that such action is not specific.

A peculiar property of cobalt (in either metallic or ionic form) is its ability to produce a polycythemia when ingested or injected.⁶⁹ This cobalt polycythemia has been produced in rats, mice, guinea pigs, rabbits, dogs, pigs, chickens and frogs. Indicative of the small concentrations in which cobalt acts is the fact that 0.04 to 0.05 mg in the entire body of a rat is sufficient to produce polycythemia.⁷⁰ It is a true polycythemia

with an increased blood volume resulting from the increase in red blood cells and with little alteration in the total and differential leukocyte counts.⁷¹ The action of cobalt appears to be on the erythropoietic centers, since hyperplasia⁷² and stimulation of the erythrogenic precursors in the bone marrow⁷³ and an initial increase in reticulocytes⁷⁴ have been observed following its administration. The spleen plays no essential role in the phenomenon. The polycythemia has been maintained for months in dogs⁷⁵ and rats.⁷⁶

Ascorbic acid can prevent or reduce the polycythemia of cobalt in rabbits⁷⁷ and dogs⁷⁸ but has no effect on that produced by anoxia.⁷⁹ Liver choline and certain vasodilator drugs have also been found effective in reducing the level of cobalt polycythemia in dogs.⁷⁸ When fed to rats, liver did not reduce cobalt polycythemia but, on the contrary, increased it.⁸⁰

The interesting observation has been made recently that the sulfur containing amino acids, methionine, cystine and cysteine, particularly the latter, prevent the toxic effects induced by cobalt and nickel administration.⁸¹

Frost and his collaborators⁸⁰ have found that the polycythemia of adult dogs on a mineralized milk diet supplemented with cobalt is only temporary, in young dogs cobalt has more toxic effect with little influence on the blood picture. These investigators have made the interesting finding that an inhibition of the normal hemopoietic response to iron and copper resulted in dogs made anemic and fed cobalt prior to the administration of the iron and copper. Hemopoietic activity was dramatically resumed on the feeding of whole dry liver or liver extract. The factor or factors in liver causing this response have not been determined. These investigators suggest that, under the conditions of the experiment, cobalt feeding creates an unnaturally large demand for certain hemopoietic precursors. The possibility that liver contains something more than iron and copper which is intimately concerned with the stimulation of hemopoiesis recalls the finding of Filmer and Underwood⁸² that the curative properties of whole liver in the treatment of enzootic marasmus (a cobalt deficiency disease in sheep and cattle) could not be

accounted for on the basis of the cobalt content, they suggested at that time that liver provides some necessary organic factor for the elaboration of which cobalt is required.

Copper deficient rats fail to develop polycythemia when fed cobalt.⁸³ Schultze⁸² has shown that cytochrome oxidase activity is diminished in copper deficient rats and fails to respond to cobalt alone, whereas the feeding of cobalt to animals receiving copper causes a rapid increase in the cytochrome oxidase activity in the bone marrow.

The knowledge that cobalt is biologically essential is the result of research carried out in Australia and New Zealand. The story of this work has been reviewed in some detail recently,⁸³ consequently, only a brief summary is needed here.

In certain parts of the world cattle and sheep have been afflicted for long periods with a disease manifested by progressive emaciation and anemia. Western Australia has had its "Denmark disease" or enzootic marasmus, South Australia its "coast disease," New Zealand its "bush sickness," Scotland its "pine disease," Kenya its "nakrutis" and Florida its "salt sickness."

Deficiency of iron had been regarded as the cause of all these diseases for some years, but in 1933 this view was questioned because of the unevenness in response to various iron compounds. In addition Underwood⁸⁴ in 1934 discovered that the livers and spleens of affected animals contained excessive amounts of iron, hardly a condition associated with deficient iron intake. The iron deficiency theory was completely discredited by Filmer and Underwood,⁸⁵ who demonstrated that by using an iron free extract of limonite, a hydrated ferric oxide used extensively in treatment, they could cure enzootic marasmus, implicating some contaminant of the iron compound as the curative factor. In 1935 Marston⁸⁶ and Lines⁸⁷ and almost simultaneously Underwood and Filmer⁸⁸ found that cobalt was the curative agent in "coast disease" and enzootic marasmus. Lines⁸⁷ and Marston⁸⁶ had been led to try cobalt through the Waltner's⁸⁹ work on cobalt polycythemia. In 1936 Askew and Dixon⁹⁰ in New Zealand found cobalt effective in the treatment of bush sickness. Cattle and sheep suffering from Florida salt sickness,⁹⁰ Kenya nakrutis⁹¹ and Scotch pine sickness⁹² have since been treated successfully with small amounts of cobalt. Certain areas of western Canada and of Michigan are now reported to have sheep suffering with

cobalt deficiency⁹³ The deficiency may be complicated by a lack of other elements Salt sickness may be associated with an iron and copper deficiency, and there have been sporadic outbreaks in areas with coast disease of an ataxia in young lambs resulting from central nervous system degeneration which can be prevented by administration of copper⁹⁴

Demonstrating once more the quantitative or perhaps qualitative differences in requirement for trace elements that exist among different species is the fact that horses can remain healthy on cobalt low pastures on which sheep and cattle develop severe deficiency symptoms Cobalt deficiency has as yet not been produced in rats even with daily intakes as low as 0.0006 mg of cobalt,⁹⁵ this element may be essential to this species but in still smaller amounts

The anemia that developed in rats on a whole milk diet responded no better to administration of iron, copper and cobalt than to iron and copper alone⁹⁶ The results when dogs were used were not so simple,⁹⁶ in many cases iron and copper alone were able to cure the anemia produced by restriction to a whole milk diet or by hemorrhage but, in about an equal number of dogs treated with iron and copper in which blood regeneration was unusually slow, small amounts of cobalt stimulated hemopoiesis

The requirements for cobalt by man are unknown The use of this element in the treatment of human anemia has been reported for children⁹⁷ with some favorable results and for adults⁹⁸ with negative results The adult cases were very few in number Waltner⁹⁹ has reported that in children, in contrast to experimental animals, cobalt administration results in an increase in the erythrocyte count but in no increase in hemoglobin

Cobalt shares with manganese the ability to activate in vitro a number of enzymes¹⁰⁰ It has not been implicated as the physiologic ion in any enzyme system

ZINC

Although several of the earlier investigators¹⁰¹ claimed to have shown the importance of zinc in nutrition, unequivocal proof for its necessity awaited the work of Todd, Elvehjem and Hart¹⁰² in 1934 Using i

dict containing only 16 parts per million of zinc, they found that the growth of the deficient rats was much inferior to the controls and that an alopecia developed over various parts of the body With still more effective diets the Wisconsin investigators¹⁰³ have produced greater differences in growth and have again observed changes in the fur The need for zinc in rats has been confirmed,¹⁰⁴ and it has been shown that mice require the element¹⁰⁵ Microscopic study in instances of the deficiency¹⁰⁶ revealed extreme parakeratosis of the esophagus with a thick layer of partially keratinized cells, the skin showed hyperkeratinization thickening of the epidermis and loss of hair follicles with persistence of the sebaceous glands Several animals showed corneal vascularization similar to that described in riboflavin deficiency¹⁰⁷

The physiologic role of zinc has been under intensive investigation Scott and Fisher¹⁰⁸ have reported its occurrence in insulin, this close association has been confirmed¹⁰⁹ Zinc¹¹⁰ (as well as some other elements¹¹⁰) reduces the severity of insulin hypoglycemia while prolonging it Scott and Fisher¹¹¹ found that the average zinc content of the pancreas of diabetic patients was only half that of the nondiabetic while the insulin content was only one fourth However, a recent report¹¹² indicates that on a fat free weight basis the zinc content of the pancreas of the diabetic and the nondiabetic is the same

Carbonic anhydrase the enzyme which accelerates the reaction $\text{H}_2\text{CO}_3 \rightleftharpoons \text{CO}_2 + \text{H}_2\text{O}$,¹¹³ appears to be a zinc-protein compound,¹¹⁴ although reports vary as to the zinc content¹¹⁵ It has been found in the blood, gastric mucosa,¹¹⁶ pancreas¹¹⁷ and renal cortex,¹¹⁸ apparently all of the zinc in the erythrocytes is in this

enzyme,¹¹⁹ which, incidentally, is inhibited by sulfamimide¹²⁰. The enzyme uricase may also contain zinc.¹²¹

In view of these findings, it is interesting to note the observations on the physiology of zinc deficient animals. Thus far there have been found no disorder of carbohydrate metabolism,¹²² no significant decrease in the carbonic anhydrase activity¹²³ and no decrease in the concentration of uricase.¹²⁴ On the other hand, the deficient rats showed a persistent rise in plasma uric acid,¹²⁴ a definite delay in intestinal absorption, particularly of nitrogenous products,¹²⁵ associated with decreases in pancreatic tryptic activity (nonspecific) and intestinal phosphatase activity.¹²⁵ Catalase activity in liver and kidney is decreased in zinc deficient mice.¹⁰⁹

If its concentration in many tissues and foods is taken as the criterion, zinc should not be classified as a "trace" element if iron is not, since it occurs in amounts approximating those of iron,¹²⁶ in some cases zinc occurs in greater concentrations, milk, for example, containing 3 to 4 mg per liter. The average daily diet contains 12 to 20 mg of zinc, almost all being excreted in the urine. For the present there is no information on the zinc requirement of man. Several balance studies, one on children of preschool age¹²⁷ and the other on children 8 to 12 years old,¹²⁸ have shown zinc retention, indicating possible requirements. Scoular¹²⁷ tentatively recommends 0.307 mg of zinc daily per kilogram of body weight for the preschool age child.

FLUORINE

The consideration of fluorine in any discussion of trace elements is pertinent for at least two reasons: first, because of the undesirable effects associated with widespread chronic fluorine intoxication, and, second, because of the recent interest in the effect of fluorine on the incidence and severity of dental caries.

Fluorine associated with various minerals is widely distributed in nature, especially in areas rich in phosphates, aluminum and volcanic ash. It is present normally in very small amounts in plant and animal tissues. McClure¹²⁹ has collected data on the fluorine content of foods and vegetables.

Water passing through fluorine rich mineral deposits becomes contaminated with the element, and consumption of this water during the period of tooth formation, particularly of the permanent teeth, results in a disease known as chronic endemic dental fluorosis, commonly called mottled enamel. Recognition that the disease

is water borne came¹³⁰ in 1916, but it was not until 1931 that three independent investigations¹³¹ implicated fluoride as the causative agent. Epidemiologic studies and animal experimentation fully support this view. Surveys of populations¹³² indicate an orderly uniformity in the group response to the fluoride concentration of the communal water supply with regard both to the incidence and to the percentage distribution of the severity of the mottled enamel, particularly the latter, as shown in the table. Amounts of fluoride not exceeding one part per million of water are not considered of public health significance.¹³³

The widespread occurrence of mottled enamel in the United States is indicated in figure 1. Its distribution is worldwide.

As fluorine acts during the period of calcification, the teeth of the affected child erupt showing characteristic signs. Instead of having the normal smooth lustrous, translucent appearance, the teeth have dull chalky white patches distributed over the surface, and in some cases the whole tooth surface may present a dead white unglazed appearance. In addition there

Relation of Fluoride Concentration to Incidence of Mottled Enamel in Children

(Nichols M. S.¹³² from data of Dean and Elvelev¹³¹)

City and State	Fluoride Content in Parts per Million of Drinking Water	Composite of 9 to 11 Year Old Children	
		Number of Children Examined	Incidence per 100 Children
Junction City Kan	0.7	110	1.7
East Moline Ill	1.5	110	4.5
Webster City Iowa	1.6	72	9.4
Clovis N. M.	2.2	108	11.0
Plainview Texas	2.9	77	87.0
Amarillo, Texas	3.9	119	89.5
Conway S. O.	4.0	50	88.1
Lubbock Texas	4.4	164	97.6

may be discrete or confluent pitting of the enamel. The affected teeth often take on a characteristic brown stain, the frequency of occurrence increasing with age. Mottled enamel is a permanent disfigurement (figs. 2, 3, 4 and 5). The microscopic appearance is that of a hypoplasia of the enamel and dentin. There is a failure in the development of the cementing interprismatic substance of the enamel¹³⁴ with incomplete calcification of the enamel rods¹³⁴ and of the dentin.¹³⁵ Pitting is the result of the breaking off of the end of the enamel prisms.

The solution to the problem lies in the reduction of the fluoride intake by a change in the community water

supply,¹³⁶ by dilution of high fluoride waters or by treatment of the water to remove the fluorides.¹³⁷ Various aspects of endemic dental fluorosis have been reviewed in a number of recent papers.¹³⁸

Chronic fluorine poisoning may occur through exposure to dusts or fumes of fluoride containing minerals used in industrial processes. Roholm¹³⁹ in his monograph reviews the literature and discusses the poisoning of workers in Copenhagen factories where cryolite (Na_3AlF_6) was used in the production of aluminum. Gastric, intestinal, cardiac and respiratory disturbances were prominent, and osteosclerosis was the outstanding feature. All the bony system was affected eventually, but the vertebral column and pelvis were affected first and most severely. Greenwood¹⁴⁰ in his comprehensive review of the recent literature also discusses acute and chronic fluoride poisoning.

Another possible source of chronic poisoning may be the use of fluoride containing insecticides used in

of the bones and teeth and of the overgrowth of the maxillary incisors following excessive erosion of the opposing mandibular incisors.¹⁴¹ have been confirmed by numerous investigators who have added to our knowledge. The use of natural phosphates or super phosphates with high fluoride content as mineral supplements to farm animals has frequently resulted in chronic fluoride poisoning. Stunting of growth, emaciation, lameness due to bone abnormality and fragility, and tooth changes similar to those of human dental fluorosis have been described.¹⁴¹

Additional evidence for the action of fluorine as a modifier of calcium and phosphorus metabolism is the observation¹⁴² that fluoride decreases the severity of rickets in rats, prolongs the life of rachitic rats¹⁴³ and causes an unorganized calcification when vitamin D is given.¹⁴⁴ When administered together with vitamin D to rachitic rats, it inhibits the healing process. Fluoride given to the normal mother causes delay and some

disorganization of calcification of the bones of suckling rats.¹⁴⁵ Greenwood¹⁴⁶ cites recent reports that pathologic bone changes occur in people living in endemic mottled areas for long periods of time. However, in a recent radiologic study¹⁴⁷ of persons in two Illinois communities, where the water supplies contained 1.5 to 3 parts per million of fluoride and where dental fluorosis was widespread, no demonstrable skeletal sclerosis occurred even though the water was taken for long periods. Smith¹⁴⁸ was unable to find any bony changes in children with mottled teeth and suggested that teeth are much more sensitive to fluoride than the bony skeleton.

Fluoride is known as an enzyme poison specifically inhibiting the formation of phosphopyruvate from phosphoglycerate. The reports in the literature on its effect on phosphatases *in vivo* are conflicting.¹⁴⁹ *In vitro* experiments indicate an inhibition of phosphatases¹⁵⁰ and esterases.¹⁵¹

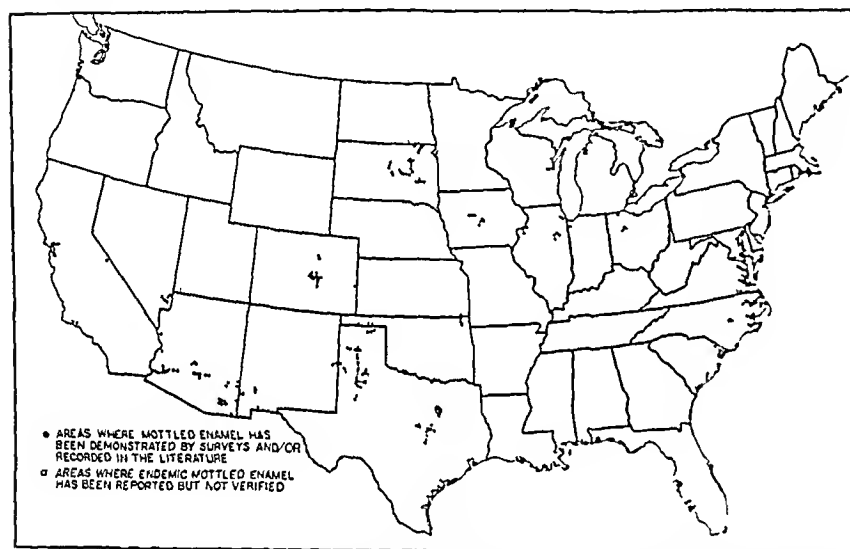

Fig. 1—Distribution of mottled enamel in the United States. In August 1938 there were about three hundred and seventy five known areas divided among twenty six states where this condition occurred in varying degrees of severity (Dean and McKay¹³⁸).

spraying fruits and vegetables. This has necessitated a federal legal tolerance on such spray residues of 7,000 grain of fluorine per pound of food, which is equivalent to about 29 parts per million.

McCullum and his co-workers¹⁴¹ and Schulz and Lamb¹⁴² first showed the detrimental effects of the inclusion of fluoride in the diet of experimental animals. Their observations¹⁴¹ on the bleaching and fragility

phosphates *in vivo* are conflicting.¹⁴⁹ *In vitro* experiments indicate an inhibition of phosphatases¹⁵⁰ and esterases.¹⁵¹

The synergistic action of thyroid and fluoride has been noted. Fluoride when given in conjunction with thyroid accentuates the effect on the basal metabolic rate produced by the thyroid, whereas the fluoride alone has no effect.¹⁵³ Fluoride enhances the toxicity of thyroid in chicks and vice versa.¹⁵⁴ Thyroid and thyrotropic hormone likewise enhance the bleaching of rat incisors by fluoride.¹⁵⁵

The fluoride content of cow's milk is only slightly affected by increasing the fluoride intake—the milk level remaining appreciably below toxic levels.¹⁵⁶ However, it is possible that women exposed to fluorides may be able to transmit enough fluoride in their milk to affect the developing teeth of the infant.¹⁵ From the somewhat meager evidence¹⁵⁸ it would appear that food is relatively unimportant compared to water as a source of this element. The question has been presented^{158a} of the possible danger of chronic fluoride poisoning arising from the use of dicalcium phosphate as a dietary supplement during pregnancy and for infants and children.

Fluorine has become of even greater nutritional interest and importance since the discovery of Armstrong¹⁵⁹ and Armstrong and Brekhus¹⁶⁰ that the enamel of sound teeth contained more fluorine than that of carious teeth, their average values being 0.0111 and 0.0069 per cent respectively. This is the only element whose concentration has been found to differ between normal and carious teeth, and the suggestion was made that the increased fluorine content might play a role in the resistance to caries.

Numerous papers have since appeared of a chemical, clinical and experimental nature with supporting evidence for a relationship between fluorine and the incidence of dental caries. It is interesting to note that before the finding of Armstrong and Brekhus there were many observations in the literature¹⁶¹ pointing out a decreased severity of caries in areas of endemic dental fluorosis.

Dean and his co-workers¹⁶² have published a valuable series of papers concerned with human epidemiologic studies. They indicate an inverse relationship between the fluoride concentration of the water supply and the incidence of dental caries in children. It is significant that in communities with a water supply containing fluorides in concentration but slightly above the minimal threshold of endemic dental fluorosis (10 part per million) and where the incidence of mottled enamel was low, the dental caries experience was much less than in communities using fluoride free water.¹⁶³ Earlier work¹⁶² had shown the inverse relationship between endemic dental fluorosis and dental caries, but

Fig 3—Mottled enamel of moderate degree. Note the whiteness, pigmentation, pitting and lack of luster particularly noticeable in this illustration and in figure 4.

the later results indicate that the limited immunity to dental caries is not dependent on the presence of macroscopic mottled enamel. The results at Bauvite, Ark.¹⁶⁴ indicate that exposure to high fluoride water for only the first several years of life resulted in increased resistance to caries for at least several years after a change to a low fluoride water supply. In all

the studies the salivary *Bacillus acidophilus* counts reflected the dental caries rate. Evidence that the problem needs further study is given in the recent report^{164a} of a study of school children exposed for two years to a domestic water which was increased in fluoride content from 0.1 to 0.7 parts per million. The dental caries experience rate and the *L. acidophilus* counts were similar to those in communities with fluoride-free water.

Recent investigations with rats show that fluorides can greatly inhibit induced dental caries when administered either during tooth development¹⁶⁵ or after formation of the teeth.¹⁶⁶ The mechanism by which

Fig. 4—Mottled enamel of severe degree. The pigmentation occurs after tooth eruption and increases with age.

Fig. 5—Normal enamel

fluoride acts is not completely established, but it appears to be by one or both of the following: (a) by the fluoride entering the tooth structure and giving it caries resistant properties or (b) by inhibiting bacterial action on food particles and on the tooth. There is evidence for both views.

Fluorides in minute amounts limit acid production by mouth bacteria, as do fluorosed and fluorine treated enamel and dentin, in larger amounts growth is inhibited.¹⁶⁷ In vitro and in vivo acquisition of fluorine by teeth has been studied,¹⁶⁸ it has been found that enamel and dentin can acquire fluoride and that treated samples show reduced solubility,¹⁶⁹ although apparently the amounts of fluoride present in slightly fluorosed teeth are too small to alter their acid solubility. Arnold and McClure¹⁷⁰ have found that subcutaneous injection of fluoride as contrasted to oral administration produced no significant reduction in induced dental caries of rats, although the fluoride content of the teeth increased, they believe that these results show that if fluoride acts by affecting structure it must be introduced during the period of tooth development.

Fluorine's concomitant effect of mottling enamel even in minute amounts unfortunately means that for the present at least its use as an inhibitor of human dental caries is most decidedly in the experimental stage. It remains to be seen whether topical application of fluoride or its intake by persons whose permanent teeth have already formed are effective and safe means of inhibiting dental caries. One recent preliminary report on topical application to a small number of cases over a period of only one year is optimistic.¹⁷¹

There is no evidence from the investigations with fluorine-low diets¹⁷² that this element is essential. However, more refined nutritional experiments or the elucidation of its role in tooth and bone structure may show that it is necessary.

SELENIUM

Selenium poisoning has gained prominence as a problem in livestock nutrition and as a possible health hazard to man since 1933, when selenium was found¹⁷³ in samples of wheat which had previously been shown to be toxic to livestock and to laboratory animals.¹⁷⁴ The ingestion of selenium bearing vegetation has thus been thought to be concerned with the pathologic conditions of farm animals known as "alkali disease" and "blind staggers."¹⁷⁵ Plants growing in seleniferous areas often contain high concentrations of the element in some organic form and presumably in the protein

friction¹⁵ The affected localities are limited in size but widely scattered throughout the Great Plains of the western United States.^{1,6}

Selenium poisoning results in stunting of growth, emaciation, loss of hair, decreased reproductive power, atrophy and cirrhosis of the liver, gastric damage and anemia.¹¹ Cattle, hogs and horses develop erosion of the bones, abnormalities of the hooves, and atrophy of the heart in the chronic form of the poisoning ("alkali disease").¹¹ The eggs of poisoned poultry have a low hatchability because of the abnormal development of the embryos into monstrosities.^{17,8} Experiments with various species have demonstrated^{17,9} that daily ingestion of selenium in amounts as low as 0.2 mg per kilogram of weight causes minor symptoms and that doses in excess of 1 mg per kilogram daily are dangerously toxic. The natural plant toxicant is less toxic than the inorganic salts but the symptoms are the same. It is noteworthy that within certain limits the toxicity of plant and inorganic selenium is determined by the protom-selenium ratio in the diet rather than by the selenium intake.^{18,0} Selenium compounds inhibit cellular respiration probably by poisoning enzymes, such as succinodihydrogenase, which are dependent on sulfhydryl groups for activity.^{18,1}

Persons living in rural areas where selenium is endemic absorb selenium in sufficient amounts to excrete it in concentrations^{18,2} much greater than those found in nonseleniferous areas.^{18,3} Analysis for selenium revealed its widespread occurrence in animal as well as plant foodstuffs from seleniferous localities. There is no definite clinical evidence of human selenium intoxication in these areas, but there is suggestive evidence that man is not immune.^{18,4} The seriousness of selenium poisoning in these populations is undoubtedly reduced by the fact that much of the flour and vegetables consumed come from nonseleniferous regions.^{18,4}

BORON

Although boron is known to be essential for plants there is as yet no experimental evidence that it is necessary for animals. It appears to exist normally in small

amounts in animals,^{18,5} in milk^{18,6} and in eggs.^{18,7} Numerous investigators have observed the rapid urinary excretion of the element.^{18,8} Two recent studies^{18,9} have shown that rats can thrive on diets extremely low in boron (less than 0.8 microgram per rat daily).

ALUMINUM

The use of aluminum in cooking utensils and in baking powders has centered more attention on its possible toxicity than on its role in normal metabolism. The evidence indicates that ingested aluminum is absorbed in but small amounts^{19,0} and that the amounts occurring in the usual human dietary (about 12 to 13 mg daily^{19,1}) are not harmful.^{19,2} This element is widely distributed in nature and has been found to occur in very small amounts in plant and animal tissues and in milk.^{19,3} It is not definitely known at present whether or not aluminum is a dietary essential. Rats maintained for six weeks on a diet containing as little as 1 microgram of aluminum daily appeared normal,^{19,3} nevertheless when the aluminum intake was increased there was definite absorption and storage. On the basis of balance studies with young children, Scoular^{19,4} suggests that this element is not essential.

CONCLUSION

Six trace elements, namely iron, copper, iodine, manganese, cobalt and zinc, have been demonstrated to be essential to animal life. Our knowledge of the human requirement for manganese, cobalt and zinc is so meager that the possibility of deficiency of any one of them occurring cannot be dismissed, although, because of their broad distribution in nature and probably small requirement, the likelihood of any acute or widespread deficiency appears remote. The essential trace elements and the other trace elements which occur in living matter but whose importance is unknown stand as a challenge to nutritionists and physiologists. The indispensable "traces," just as the vitamins, appear to be keys to fundamental physiologic processes the mechanisms of which are either only partially understood or in most cases completely unknown.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF
THE FOLLOWING ARTICLE HOWARD A. CARTER, Secretary

THE THERAPEUTIC VALUE OF ULTRAVIOLET RADIATION

The Council on Physical Therapy recognizes the place of ultraviolet radiation therapy in medical practice. However, it is also cognizant of the fact that this type of therapy is often exploited beyond its limitations. The following statements set forth the views of the Council with respect to the conditions in which ultraviolet radiation therapy is of benefit.

Either natural or artificial heliotherapy is used. The artificial sources of therapeutic ultraviolet radiation are the carbon arc lamp, the low voltage (hot) mercury vapor lamp and the high voltage (cold) mercury glow lamp. For further information on the artificial sources of ultraviolet radiation the reader is referred to the chapter 'Sources of Ultraviolet and Infra Red Radiation Used in Therapy—Physical Characteristics' by W. W. Coblenz, Ph.D., D.Sc. in the Handbook of Physical Therapy, a publication of the American Medical Association.

VITAMIN D¹

Ultraviolet irradiation with wavelengths shorter than 3130 (particularly 2967) angstroms exerts an influence on calcium and phosphorus even when the diet is adequate. But of even greater importance from the standpoint of protection against dietary deficiencies is the action of ultraviolet radiation in rectifying partial lack of the components necessary for proper calcification of bone and teeth.²

From the provitamins in the skin, ultraviolet irradiation gives rise to vitamin D, the agent which promotes normal calcium anabolism and retention of phosphorus. Therefore, it may prevent and cure rickets, adult as well as infantile, promote growth and prevent excessive loss of lime from the body. It is necessary not only for the development of teeth but for their protection later in life.

Ultraviolet irradiation may be used in the treatment of infantile tetany, a symptom complex occurring in rickets when the blood calcium is low. The treatment of choice is a combination of a calcium salt (lactate or gluconate), a diet low in phosphate and optimal vitamin D.³ Latent tetany may become manifest when rachitic infants are irradiated if sufficient calcium is not available, owing to the suddenly increased mobilization and deposition of calcium in the growing bones.

While irradiation of parathyroidectomized animals and man will keep them free from tetany, administration of vitamin D itself is far more efficient.

When an animal is irradiated, its skin, liver, fat and muscle become antirachitically active.⁴ Ultraviolet radiation forms vitamin D either in the cells of the living organism or in its food stuffs. Direct exposure of the skin to ultraviolet rays from the sun or from artificial sources results in the formation of vitamin D within the organism but the Council cannot recognize statements or implications that ultraviolet radiation from an artificial source has all the beneficial effects of exposure to sunshine.

The Council on Foods and Nutrition has made the decision that for the present milk is the only common food which will be considered for acceptance when fortified with vitamin D.

One of the methods used to impart antirachitic properties to accepted vitamin D milks is irradiation with ultraviolet shorter than 3130 angstroms. Activation depends on the same wavelengths effective directly in the cure and prevention of rickets.

Vitamin D in some way regulates the passage of calcium and phosphorus across the intestinal wall. It exerts its action by raising the blood calcium and/or phosphate. This is associated usually with an increased net absorption from the intestine, though under certain circumstances the bones may provide the calcium and phosphate. The net retention of the animal as a whole is the resultant of two opposing factors: (1) increased absorption from the intestine or diminished excretion to it and (2) increased excretion by the kidney. As the dosage of vitamin D becomes larger, the second factor overtakes the first.

TUBERCULOSIS⁵

Both natural and artificial ultraviolet radiation are of definite value in the treatment of some forms of tuberculosis. There is still considerable difference of opinion on which regions of the light spectrum are most efficacious as well as confusion as to the tuberculous conditions that respond best to this treatment.

Natural heliotherapists, especially those working in high altitudes, emphasize solar radiation and acrotherapy. On the other hand, those in cloudy climates have stressed the use of artificial lights and still others, on occasion, the x-rays.

The physiologic effects of radiant heat energy suggest that clinical results of therapy with sunlight are at least in part dependent on the red and infra-red region. Most recently the response of certain forms of superficial tuberculosis, especially of the skin, to heat radiation speaks very clearly for this.

The exact part played in the clinical usage of radiation by the total visible spectrum is difficult to say, although in all probability it is in some way physiologically effective.

In tuberculosis on the basis of the quality of ultraviolet wavelengths and of the results obtained at the seashore, at inland sea level and in the mountains, Danish workers are convinced that ultraviolet energy of the region longer than 313 millimicrons is the one effective in the treatment. The additional part played by the action of moving air on the skin in the solar treatment of extrapulmonary tuberculosis must not be discounted. Probably the combination of all factors contributes to the end result.

The radiations of artificial sources represent approximations to sunlight and no two sources are alike in respect to the distribution of the energy they emit. Therefore different sources do not produce the same physiologic or therapeutic action. The energy emitted by various artificial sources varies in intensity and in spectral distribution. The intensity of the radiation of sunlight on the earth's surface varies considerably, particularly on account of location, season and time of day. It will vary as much as 5 per cent in total intensity and a variation of five to ten times in noon hour ultraviolet winter to summer.

For therapeutic purposes the sun, the mercury vapor arc in quartz and the flaming carbon arc burning cored carbons filled with mixtures of carbon dust and metals have been found to be most practical. The mercury vapor lamp has been particularly developed for its emission of ultraviolet although it also emits well in the visible part of the spectrum. Its ultraviolet component represents between 9 and 28 per cent of the total energy of all wavelengths emitted by the lamp. A carbon arc consuming 25 amperes or more and burning specific carbons such as 'sunshine' carbons, closely approximates highland sunshine. Carbon arcs of varying amperage and with special cored carbons will emit, almost according to the needs, widely varying intensities in many regions of the spectrum.

An important question in the selection of these various sources of light is the minimum ultraviolet radiant power that a source must emit in order to insure effective therapeutic action. The amount of ultraviolet that can be applied to the body without producing a burn depends on the tolerance of the skin. The erythral reaction is really the only physiologic one that is established with a relatively high degree of accuracy. As a

criterion it is a simple and practical means of preventing severe burns and as a reaction it is a good means of judging the effectiveness of a lamp.

The conditions, clinical and otherwise, indicating the selection of one source of light in preference to others depend in part also on the convenience of usage, the availability of the source of light and the cost of running. In the past, carbon arc lamps of high amperage have been more generally applied for exposures of groups. The mercury quartz lights are now applicable for exposures of groups as well as individual patients. The carbon arcs of lower amperage, as well as mercury arcs, can be used for single patients. Irradiation with artificial light, as ordinarily employed indoors, lacks some apparently important accompaniments of outdoor solar exposures, such as constantly moving fresh air.

Pulmonary Tuberculosis—For uncomplicated pulmonary tuberculosis, no clinical evidence is at hand to prove the indication for ultraviolet radiation. The lack of accurately controlled observations among certain workers makes it necessary to accept their favorable reports most cautiously. Until contrary evidence is at hand, ultraviolet irradiation is contraindicated in the treatment of uncomplicated exudative pulmonary tuberculosis. Sunlight or artificial light, if employed at all, should be used cautiously in the treatment of proliferative or fibrotic pulmonary tuberculosis, which may be accompanied by elevation of temperature. Intense sunlight should be avoided, and diffuse daylight or early morning and late afternoon sunlight should be watched for. The indications here resemble those of tuberculin therapy.

In pulmonary tuberculosis, even when quiescent, harm has been done by sunlight exposures, especially with too intense and prolonged irradiations. Solar heat alone especially in summer, can prove very exhausting. An observing patient will note fatigue, exhaustion, irritability or even overstimulation after these solar baths. With this reaction, sunlight should be discontinued. If symptoms are due to overdosage only, exposures may be resumed after an interval, shorter or less intense exposures being employed. Increase of local symptoms such as cough and expectoration, and pleurisy, or of systemic symptoms, such as elevated pulse and temperature, serves as a guide. In these cases it may be advisable to substitute irradiations of diffuse daylight of longer duration, or of low intensity sunlight in the early morning and late afternoon hours.

In an active febrile pulmonary tuberculosis complicated by active intestinal tuberculosis, mercury quartz irradiations have been regularly used by many for the intestinal complication and not infrequently with favorable effect. In such cases the activity and nature of the pathologic changes of the pulmonary disease have been disregarded. The favorable empirical results thus obtained and the poor results obtained when other treatments have been used justify this as an indicated therapy.

For other forms of active extrapulmonary tuberculosis, such as that of bones and joints, or lymph nodes complicating active pulmonary tuberculosis, light exposures have been often used to advantage, so that the pulmonary disease, if not rapidly progressive, offers no contraindications. However careful observations, especially in exudative forms of pulmonary disease, will not rarely reveal the development of harmful pulmonary focal reactions due to excessive exposures to ultraviolet. This should deter one from exposing such patients indiscriminately.

Focal reactions have been shown to occur in the lungs even when direct sunlight is reflected in overdosage on a tuberculous larynx. Some workers observed their occurrence when the limbs alone were irradiated with the mercury quartz and carbon arc lights. In the use of both lamps and sunlight one often notices on beginning treatment a slight elevation of temperature with mildly increased focal pulmonary symptoms. This reaction has been likened by some observers to a tuberculin reaction. A focal reaction such as has been observed in the lungs, larynx and joints has been obtained in cases in which good pigmentation developed. A latent period always exists before signs of the reaction appear. By the screening of lupus areas from the light and exposing the rest of the body the diseased tissue has often healed indicating apparently the

transport by the blood of some substance to the focus. However, therapy is preferably carried out by exposing the diseased parts in addition, because the local inflammatory reactions obtained through direct irradiations may be of importance.

Harm due to irradiation of patients with pulmonary tuberculosis results almost always from an indiscriminate use of ultraviolet radiation, with overdosage. It may be manifested with increased local symptoms, namely, increased cough and expectoration, localized pain, blood streaked sputum or hemoptysis and following these, fever and tachycardia.

Pleural Tuberculosis—Pleural tuberculosis, dry or serous, especially if it is the initial clinical manifestation, is occasionally aided by ultraviolet therapy. The acute serous form is not to be irradiated. A tuberculous pleurisy with no obvious pulmonary disease usually responds to ordinary rest and hygienic-dietetic treatment, cases not responding after about a month of such treatment may call for irradiations. Pleuritis occurring in the course of obvious pulmonary tuberculosis, as well as pneumothorax cases, offer the same indications as the lung disease. Tuberculous empyemas do not respond. If sinuses are infected, they are rarely helped by local and general ultraviolet applications. Pleural tuberculosis in the Negro, peculiarly enough, has been cited as favorably responsive to ultraviolet radiation.

Laryngeal Tuberculosis—Laryngeal tuberculosis is practically always secondary to pulmonary tuberculosis, so that the indications for the treatment of the larynx depend on the nature of the disease in the lungs. Here again ultraviolet by itself is not curative but exercises its part only as an adjuvant to the other mainstays of treatment. General ultraviolet light exposures are made to the body, with at times additional laryngeal local exposures. The acute forms of laryngeal tuberculosis, particularly those with edema, are not indications for ultraviolet therapy. Exposures of ultraviolet radiation are made with the aim of producing a mild focal reaction, the reaction being allowed to subside before the next exposure is made. Those patients in whom mild focal reactions developed through irradiation showed often a greater tendency to heal, but no advantage to be gotten from a local treatment to the larynx is cause enough to compel a patient to leave his bed when his active disease indicates bed rest. Furthermore, general body irradiation in this complication plays a large part. Local ultraviolet therapy has proved useful as a postoperative measure in cauterization cases, and as a sedative measure in cases in which cauterization cannot be done.

Tuberculous lymph nodes may be seen clinically in three different stages, namely, as enlarged nodes which have undergone hyperplasia, as nodes which have proceeded to the stage of caseation and softening, or as softened nodes which have perforated to the exterior through a sinus tract. In the first stage general body exposures to repeated erythema doses of ultraviolet radiation are not infrequently followed by an inflammatory reaction at the nodes with slight pain, tenderness and swelling. In the majority of cases the inflammation subsides and the lymph node finally heals. Occasionally nodes in the hyperplastic stage may become caseous under light treatment and at times may have to be treated surgically by excision. In such instances ultraviolet radiation is of great value when used postoperatively in preventing the formation of tuberculous sinuses. In the second stage of caseation light exposures alone will frequently bring about resolution. When softened lymph nodes reach the stage of fluctuation, aspiration or incision is necessary and then light is most effective. In the third stage excellent results are obtained in clearing up sinuses of long standing, but occasionally roentgen exposures may have to be combined with light treatment for complete healing to take place. Local irradiation of the sinus area should be made in addition to general irradiation of the body. In cured cases, exposures have averaged from three to eight months.

General body exposures are usually combined with those to the nodes or sinuses. In addition, repeated aspiration, when possible is made of any fluctuating node generally entering with the needle from above. At times incision into a softened node is necessary. If the nodes do not heal with these measures, x-rays are resorted to.

The prognosis will vary frequently, depending on whether the patient has also pulmonary tuberculosis and what the prognosis of the pulmonary disease alone will be.

For nodes not yet broken down, local and general sunlight or artificial light exposure, together with the application of x-rays, is the treatment of choice. In the softening stage of tuberculous adenitis treatment is first best attempted with sunlight or sunlamps and without x-rays. Aspiration is usually necessary. With sinuses, occasionally the use of radiant heat may help to close them if combined with ultraviolet exposure.

Secondary Ulcerative Intestinal Tuberculosis—Secondary ulcerative intestinal tuberculosis is the most frequent complication of pulmonary tuberculosis occurring in from 50 to 80 per cent of the patients who die of pulmonary tuberculosis as revealed by necropsis.

Artificial light and solar therapy, as well as a rich vitamin diet should be used in most cases, as they frequently relieve the symptoms and bring about recovery. When the desired results are not obtained by radiation therapy roentgen treatment of the intestinal tract should be carefully given or other additional measures employed.

Excellent results are obtained with the use of artificial sources of radiation with general exposures either of the mercury arc in quartz or of carbon arc sources. The results depend on factors such as the general status of the patient and the location, extent and nature of the disease in the intestine. Those with late advanced pulmonary and intestinal tuberculosis with little remaining resistance cannot be expected to respond but intestinal tuberculosis today is healed in many patients and necropsies have often confirmed this.

It is seen that with ultraviolet exposures and hygienic treatment the symptoms referable to the intestinal tract generally vanish during the first few months of irradiation but the exposures should be continued for at least six months to two years. The loss of symptoms is frequently surprising, abdominal pain and discomfort disappearing, diarrhea and fever subsiding, quiet and general improvement taking place. Roentgenologic studies show that the intestinal irritability is visualized by x-ray defect clears up entirely in many instances. It is usually best to continue ultraviolet therapy for many months after an apparent cure has occurred.

Peritoneal Tuberculosis—In peritoneal tuberculosis ultraviolet therapy always deserves a trial first. The serous exudative type generally responds to irradiation both in children and in adults. The dry proliferative form usually adhesive is more refractory. When there have been ulcerations and large caseous lymph nodes, as commonly seen in children the results are most unsatisfactory. When the disease is of long standing healing is more difficult than when irradiation is begun a short time after onset.

Pain under ultraviolet therapy usually disappears rapidly, especially in children. Large quantities of ascitic fluid may disappear in a few months.

Genitourinary Tuberculosis—If unilateral renal tuberculosis is diagnosed at the very onset of symptoms and when such symptoms are slight conservative treatment with ultraviolet radiation has on rare occasions prevented the need of surgical intervention. As a rule, nephrectomy is indicated for unilateral progressive renal tuberculosis or bilateral disease in which the more involved kidney is removed ultraviolet radiation is to be advised as a desirable postoperative treatment. It may have a favorable action on the genital organs and the remaining kidney and effectively contribute to the healing of a tuberculous cystitis, whether alone or in association with medical treatment. Ultraviolet therapy exercises a healing action on the stump of the ureter, which so often shows residual ulceration resulting in a discharging sinus or a persistent cystitis. It has given excellent results, even with chronic gaping wounds and tuberculous granulations. The edges of the wound are separated and held apart with broad strips of adhesive plaster to allow the ultraviolet rays to penetrate the depths and to prevent formation of a closed pocket which would favor purulent retention

as a result of a premature superficial closure. Such extensive wounds may heal with a linear elastic scar and often are hardly visible in the pigmented skin.

Ultraviolet is particularly indicated in those not infrequent cases of renal tuberculosis complicated by genital tuberculosis in which the seminal vesicles and prostate are involved, thus often obliging postponement of cystoscopy to avoid trauma of the prostate and the risks of general infection. In such cases it is imprudent to consider the kidney disorder as an independent lesion for it is but one manifestation of tuberculosis affecting the whole genitourinary system. Therefore, before surgical intervention it is advisable to treat the concomitant lesions with a methodical course of ultraviolet radiation to make cystoscopy and nephrectomy procedures of less risk of dissemination.

In bilateral renal tuberculosis, ultraviolet therapy is indicated. It may help render the disease quiescent its occasional analgesic action on ulcerations of the bladder is particularly welcome. It is in these cases of bilateral tuberculosis that advanced infection implicating the genital tract is so often encountered. While the renal lesions tend to become stationary, there is often a steady regression and improvement of the prostatic and bladder lesions and their clinical symptoms.

Advanced bilateral renal and bladder tuberculosis has rarely responded to any form of therapy especially when the patient is cachectic. Pain has occasionally been relieved by ultraviolet exposures but the frequent irritation is very resistant. Occasionally removal of the more diseased kidney has temporarily relieved the symptoms. Postoperative sinuses, especially following nephrectomy have responded in a large number of cases to ultraviolet therapy of all forms.

Circumscribed tuberculous lesions of the urinary bladder have improved under local intravesical exposures of ultraviolet radiations from the low pressure cold mercury discharge.

Bone and Joint Tuberculosis—In bone and joint tuberculosis heliotherapy although not the mainstay of treatment, is always employed in combination with other forms of therapy. Orthopedic measures rest in the open and light form the basis of conservative therapy. Combined conservative treatment includes orthopedic measures such as immobilization of joints, traction and careful use of passive and active motion, use of ultraviolet or tuberculin and diet and judicious application of surgery.

Ultraviolet therapy must be admitted to be a real addition to our resources. It is not to be expected that it will produce new cartilage in place of that which has been utterly destroyed. It does not make the process of fusion less necessary than it has been heretofore but it can help this develop. It is wrong to expect that its use will bring about regeneration of bone equal to that of a few vertebral bodies when they have been destroyed but when this has occurred and a gibbous deformity exists ultraviolet therapy has aided orthopedic treatment in taming these diseased surfaces, especially when employed together with postural treatment.

Surgical fusions are less commonly performed on children under 12 years of age. If performed on adults or children the disease must first show some evidence of retrogression thus surgery is to help nature. Following operation patients are still treated for from one to two years and during this period heliotherapy plays an important part.

Both mercury arc in quartz and carbon arc irradiation, employed in general and local exposures for prolonged periods of time have proved aids in the treatment of bone and joint tuberculosis. The technique of irradiation is the same as that described with other forms of tuberculosis. With early exposures the joints or bones often respond with increase of local swelling and pain and if a sinus is present increased secretion. These in turn subside. Small joints yield more quickly to treatment than large ones. The knee joint is refractory, and particularly obstinate are old fistulas of the spinal column, pelvis or hip. In many instances treatment should be continued for two or more years.

Other Forms of Tuberculosis—Ultraviolet ray therapy is indicated in various other forms of tuberculosis. Many manifestations of cutaneous tuberculosis respond well to ultraviolet irradiation. Tuberculous ulcers of the mouth and pharynx usually secondary to advanced pulmonary or laryngeal tuber-

culosis or to hematogenous dissemination, are most resistant. Electrocoagulation is a more effective therapy.

Aural and ocular tuberculosis are difficult to affect with ultraviolet, although corneal ulcers and phlyctenular conjunctivitis have not infrequently healed under local exposures. Roentgen therapy has proved effective with tuberculosis of the cornea and iris, but its dose must be moderate and repeated regularly at intervals of about four weeks. These measures are indicated when tuberculin therapy has failed.

RELATIVE MERITS OF DIFFERENT FORMS OF RADIATION

The following outline is constructed with the realization that as yet the relative merits are not accurately defined and not accepted by all. It is offered merely as a possible working basis.

Sunlight is available in almost every locality at some season of the year. Its intensity is variable, but moving air and low intensity sunlight or diffuse daylight can generally be used. In some places where the extreme cold of winter prevents outdoor exposures for a few months, artificial sources of light should be resorted to.

1 Uncomplicated Pulmonary Tuberculosis—(a) Sunlight is to be used only after prolonged trial of routine rest, hygienic-dietetic treatment and perhaps in cases in which surgical treatment has failed to cause satisfactory healing (exudative tuberculosis always excluded). Carefully graduated general body exposures are to be made to sunlight of low intensity or to diffuse daylight, together with air baths in the earlier morning or later afternoon hours. The so called pretuberculosis of children, as well as chronic pleuritis, are all forms in which sunlight can be the treatment of choice.

(b) Artificial lights (mercury arc in quartz and carbon arc) deserve a trial only after routine therapy has failed, but one should not expect promising results except in isolated instances. They may occasionally help as an adjuvant. Progressive cases with fever and exudative tuberculosis are excluded. Pleuritis and the "pretuberculosis" of children can be favorably influenced.

2 Active Extrapulmonary Tuberculosis Without Active Pulmonary Tuberculosis—Tuberculosis of the skin, lymph nodes, bones, joints, genitourinary tract, peritoneum, intestine. By this is meant that the signs and symptoms of active or progressive disease are due, not to the pulmonary tuberculosis, but to the extrapulmonary focus. Signs of active disease include both local and constitutional signs.

(a) Sunlight is the treatment of choice for bones and joints, lymph nodes and genitourinary tract, especially in the highlands. Graduated exposures of the body are to be made to sunlight, together with the use of rest and hygiene and whatever surgical and orthopedic measures may be necessary. Results are excellent if sunlight is employed over prolonged periods, even in active but not rapidly progressive forms of the disease. Artificial lights should be used, in addition, on cloudy days, especially in cases of cutaneous tuberculosis or discharging sinuses.

(b) Artificial lights (mercury arc in quartz and carbon arc) are to be used usually as substitutes for sunlight. However, they may be preferable to sunlight for certain complications, such as superficial, peritoneal and intestinal tuberculosis. Superficial forms include lupus vulgaris and scrofuloderma, keratitis and phlyctenular conjunctivitis. General exposures are always made with additional local exposures over the area of disease.

3 Active Extrapulmonary Tuberculosis with Active Pulmonary Tuberculosis Accompanied by Fever—Both pulmonary and extrapulmonary tuberculosis show subjective evidence of active or progressive disease.

(a) Sunlight is the treatment of choice in tuberculosis of the bones and joints and in genitourinary tuberculosis. Sunlight of low intensity in the early morning and late afternoon hours being used. The solar and air exposures should be given very gradually.

(b) Artificial lights (mercury arc in quartz and carbon arc). The mercury quartz light is often preferred when pulmonary disease is exudative and febrile, because of its great deficiency

in heat rays. Better results are then had in tuberculosis of the intestine, peritoneum, epididymis and lymph nodes. It is advisable to alternate mercury quartz irradiations with exposure to the outside air and diffuse daylight.

(c) With an acute progressive tuberculous laryngitis, ultraviolet irradiations applied locally are inadvisable until the acuteness has subsided, but if other measures have failed ultraviolet irradiations may be tried as a final treatment if only for their possible analgesic effect. Combinations of local irradiations of ultraviolet and general body exposures are always employed, if possible, according to the indications mentioned.

Benefits are undoubtedly obtained by patients suffering from tuberculosis of the bones, articulations, peritoneum, intestine, lymph nodes and larynx when the entire body is exposed to carefully graded doses of natural sunlight or to radiation emitted by certain artificial sources of light rays. The beneficial results of such irradiation are due not only to ultraviolet rays. The visible and infrared rays, as well as the conditions of the atmosphere, play a certain part in the therapeutic effect.

In tuberculosis of the skin, lupus vulgaris alone can be said to respond satisfactorily to ultraviolet irradiation. Scrofuloderma and erythema induratum react favorably at times to general and local exposure, although not as constantly.

In tuberculosis of the bones and articulations, it is generally agreed that suitable graded exposure to natural sunlight is most effective in aiding the healing accomplished by orthopedic and other measures. Exposure to artificial sources of radiation is valuable here as a second choice.

Pulmonary tuberculosis, per se, is not an indication for ultraviolet therapy, stationary pleural tuberculosis has often been helped by this measure.

Genitourinary tuberculosis deserves a trial of such treatment in combination with other measures. Local exposure to ultraviolet rays of circumscribed tuberculous lesions of the urinary bladder has been shown to yield favorable results but the method requires special applying devices and, above all, skilful treatment of the bladder lesion.

Ocular tuberculosis and aural tuberculosis respond infrequently to light. Oral tuberculosis is most resistant.

Fistulas are often resistant to such treatment. Postoperative sinuses, in contrast, are most responsive.

Intestinal, peritoneal and lymph node tuberculosis especially indicate ultraviolet therapy and often are rapidly responsive.

In tuberculosis, overdosage has produced harmful focal reactions. Here light may set up a focal reaction similar to that of tuberculin.

The erythemic reaction is an accurate indicator of skin tolerance.

Hence a preliminary exposure of a small area to gauge the minimal perceptible erythema will avoid undue burns.

SURGICAL VERSUS CONSERVATIVE TREATMENT OF BONE AND JOINT TUBERCULOSIS

With any form of tuberculosis ultraviolet is to be used merely as an adjuvant and should be combined with all other indicated forms of therapy. The mainstays of treatment, such as rest, proper dietary, and hygienic outdoor life still remain.

With bone and joint tuberculosis orthopedic measures combined with light still play the major role. Indications for surgical intervention may depend on many factors: economic and social conditions, the age of the patient, the joints involved, their number and the stage and extent of the disease, involvement of other organs such as the lungs and kidneys and complicating abscesses or sinuses. Joint tuberculosis is still a local manifestation of a constitutional disease. Surgical measures are therefore in turn to be recognized as adjuvant procedures to be followed by prolonged conservative therapy. Intervention by surgical fusion is always to be seriously considered in the presence of advanced joint destruction. Restoration of function may occur in the synovial form of joint tuberculosis, even in the presence of large effusions, but complete functional return of motion in a joint is doubtful when the bony parts have been destroyed to a considerable degree.

SATURDAY, OCTOBER 24, 1942

SUPREME COURT TO REVIEW QUESTIONS RELATED TO PRACTICE OF MEDICINE

An indictment was filed on Dec. 20, 1938 in Washington, D. C., which charged the American Medical Association, the Medical Society of the District of Columbia, two other medical societies, certain officers of the medical societies and others with conspiring to restrain the trade of Group Health Association, a corporation, in violation of section 3 of the Sherman Act. The District Court first held that the indictment did not charge the defendants with any offense known to the law, but the Court of Appeals of the District of Columbia reversed this holding and directed a trial of the case. In due course a trial was held and the jury found the American Medical Association and the Medical Society of the District of Columbia guilty and all of the other defendants not guilty.

On May 29, 1941 the District Court entered judgment on the verdict of the jury. An appeal was taken to the Court of Appeals of the District of Columbia, and that court on June 15, 1942 affirmed the judgment of the lower court. The American Medical Association and the Medical Society of the District of Columbia filed a petition in the Supreme Court of the United States asking that court to issue its writs of certiorari to review the decision of the Court of Appeals and to reverse it and to hold that there had been no violation of section 3 of the Sherman Act. By their petition for certiorari filed in the Supreme Court of the United States, the American Medical Association and the Medical Society of the District of Columbia contended that there were eight important questions presented by the record in the case wherein the trial court and the Court of Appeals committed error.

On Oct. 12, 1942 the Supreme Court of the United States granted the petition for writs of certiorari and thereby agreed to review and consider the record in the case but limited the review to the consideration of

the first three questions presented by the petition for writs of certiorari, which were:

1 Whether the practice of medicine and the rendering of medical services as described in the indictment are "trade" under section 3 of the Sherman Act.

2 Whether the indictment charged or the evidence proved "restraints of trade" under section 3 of the Sherman Act.

3 Whether a dispute concerning terms and conditions of employment under the Clayton and Norris-LaGuardia acts was involved, and, if so, whether petitioners were interested therein, and therefore immune from prosecution under the Sherman Act.

The American Medical Association and the Medical Society of the District of Columbia will now file their printed brief and argument in the Supreme Court of the United States and thereafter the case will be argued orally and the court will then consider the three questions which it has consented to review and in due course file its decision and opinion.

DIETARY HEPATIC CIRRHOSIS

The cirrhosis of the liver observed in chronic alcoholism is probably the most important of various forms. New experimental evidence developed by Gyorgy and Goldblatt¹ of Western Reserve University suggests the possibility that nutritional factors are involved in the development of this form of damage to the liver. Experimental work with animals indicates that the essential cause of alcoholic cirrhosis in man may be a low protein intake associated with a deficiency of the vitamin B complex. Three years ago the Cleveland investigators² observed that young experimental rats maintained on a diet deficient in the vitamin B complex developed acute focal or diffuse necrosis with fat infiltration of the liver, with an occasional diffuse periportal fibrosis. Indication of an infectious or toxic origin of this hepatic injury was not present, nor was the condition prevented by the daily addition to the diet of adequate amounts of thiamine, riboflavin and pyridoxine. Further experiments showed that animals could be protected from injury to the liver when small amounts of thiamine, riboflavin and choline were added to the diet deficient in the vitamin B complex. The addition of pyridoxine was without effect. Pantothenic acid also failed to produce any effect unless given early, when it was beneficial.

Further study of the observed results suggested to the Cleveland investigators the possibility that the low food intake characteristic of animals fed on diets lacking in the vitamin B complex was an essential cause of the observed hepatic degeneration followed by cirrhosis. Experiments accordingly were planned to test the hypothesis that the protein content of the diet was important in the development of the liver injury.

¹ Gyorgy, Paul and Goldblatt, Harry, J. Exper. Med. 75: 355 (April) 1942.
² Gyorgy, Paul and Goldblatt, Harry, J. Exper. Med. 70: 185 (Aug.) 1933.

Groups of animals were maintained on seven different rations, in which the essential difference was the relative amount of protein (casein) in each. The amount of casein was varied from 18 per cent in the standard diet down to as low as 5 per cent. Each ration contained 20 per cent fat, from 50 to 70 per cent of cane sugar or corn starch, 2 per cent cod liver oil and 4 per cent salt mixture. The diets were appropriately supplemented with thiamine, riboflavin, pyridoxine and calcium pantothenate.

As a test, 184 rats were put on a diet in which the routine casein ration had been reduced one half, i.e., to 10 per cent. To this modified diet a routine daily supplement of vitamin B complex factors was added in the different subgroups. Without this supplement, 75 per cent of the rats developed hepatic injury during the first one hundred and fifty days, 65 per cent of them showing cirrhosis. Addition of 20 mg of choline to the daily diet reduced these percentages by about one third, while a daily supplement of 100 mg of L-cystine increased the percentage and severity by about one third. The apparent toxic effects of cystine were neutralized by a daily administration of choline or by a daily supplement with yeast. The beneficial effects of yeast were apparent even when the low dose (0.5 Gm.) was given but three times weekly. The most severe necrosis and cirrhosis of the liver, often accompanied by ascites and pleural and pericardial effusion, were noted in groups in which the daily intake of casein had been reduced to 8 per cent.

The accumulated data from these and numerous other tests led to the tentative conclusion that under the conditions of their nutritional experiments the dietary hepatic injury was due to two factors, an insufficient protein intake supplemented by an insufficient amount of some unidentified vitamin B complex factor.

The closest analogy to these experimental conditions in human pathology would be in alcoholic addicts. Low protein intake combined with an insufficient amount of vitamin B is a prominent feature of the daily diet of most persons addicted to alcohol. The assumption of a specific toxic action of alcohol becomes superfluous in this analogy, as it is superfluous in the etiology of pellagra or beriberi of alcoholic addicts. The recent claim³ of the beneficial effect of a "highly nutritious diet" supplemented by vitamin B concentrate on alcoholic cirrhosis in man is an apparent confirmation of their suggested theory.

Experiments thus far reported by the Cleveland investigators were exclusively of a prophylactic nature. In a few animals hepatic injury confirmed by biopsy was treated by the daily administration of yeast or liver powder, thus far (two months) success has been limited. Therapeutic studies are being continued.

FUMIGATION AND HUMIDITY

The decreased effectiveness of germicidal vapors with increased humidity reported by Wells and Zappasodi¹ of the Henry Phipps Institute, University of Pennsylvania, is contrary to generally accepted views of the effects of fumigation. Seventy years ago Lister introduced his carbolic spray into the operating theater. His spray technic was gradually abandoned by surgeons as they became convinced that most surgical infections are due to bacteria introduced on the hands or instruments. Recently, however, the necessity for augmenting routine aseptic technic with precautions against air borne bacteria has again become of practical clinical interest. Among other methods of sterilization of air is the employment of germicidal mists or aerosols.

Twort and his co-workers² of Portslade Laboratories, Sussex, England, examined various phenolic mists by means of a duplex ultramicroscope which enabled them to estimate the size, speed and rate of evaporation of mist particles. The English investigators assumed that these germicidal particles act solely by collision with air borne infectious agents. They develop elaborate mathematical equations to express this rate of collision and the resulting rate and efficiency of the germicidal action. In actual tests in closed atmospheres they found that sufficiently fine mists of 10 per cent hexylresorcinol in propylene glycol gave germicidal effects in apparent confirmation of their mathematical equation. Fully evaporated mists (vapors) of this mixture were non-effective on air borne *Escherichia coli* and other routine test organisms.

Working with propylene glycol mists and air borne influenza virus, however, Robertson and his colleagues³ of the University of Chicago drew the opposite conclusion. Their studies indicated that the germicidal action is due principally to the liberation of gas by the rapid evaporating aerosol droplets and not to collisions between mist droplets and infectious particles. They found that an atmosphere containing a 1:2,000,000 dilution of fully evaporated propylene glycol would protect mice from infection with the air borne influenza virus. All 35 control mice which breathed the same contaminated air but without the addition of the germicidal gas died in from six to ten days, with typical influenzal consolidation of the lungs.

In studying the effects of the same propylene glycol vapor on air borne beta streptococci, Wells and Zappasodi at first obtained irregular and confusing results. Afterward they noted that these contradictory results were associated with humidity changes in their exposure chamber. With carefully controlled humidity experi-

1 Wells W F and Zappasodi Peter Science 96 277 (Sept 18) 1942

2 Twort C C Baker A H Finn S R and Powell E O J Hyg 40 253 (May) 1940

3 Robertson O H, Loosh, C G Puck T T, Bigg Edward and Miller B F Science 94 612 (Dec 26) 1941

3 Patek A J Jr and Post Joseph J Clin Investigation 20 481 (Sept) 1941

ments they found that high humidity almost completely neutralizes the germicidal action of propylene glycol vapor. Dehumidification had the opposite effect, increasing the germicidal action threefold. In the average of twenty-four experiments with air of medium humidity, for example, the bactericidal titer of the vapor was 1.59 lethals (an arbitrary unit "equivalent to bacterial removal by one displacement of the atmosphere within the chamber"). In control tests with highly humidified atmospheres the average germicidal titer was reduced to 0.69 lethals. In artificially dehumidified atmospheres the average titer was increased to 4.29 lethals.

Current Comment

ULTRAVIOLET ROOM STERILIZATION

A quantitative study of the efficiency of ultraviolet radiation to reduce the number of viable air borne spores in a closed room has been reported by Kligman¹ of the University of Pennsylvania. The room in question was used as a laboratory for the manufacture of "grain spawn," a heat sterilized rice grain medium inoculated with the mycelium of the cultivated mushroom *Agaricus campestris*. In commercial practice sets of one hundred and eighty milk bottles are sterilized and inoculated daily. Before attempting room sterilization there was an average spoilage of twenty bottles per set, or an 11 per cent economic loss. This average was cut to eleven bottles per set, or about 6 per cent, after an air filtration apparatus had been installed. In order to reduce the spoilage further, supplementary measures were tried, including formaldehyde fumigation. The method finally adopted was the use of two 30 inch ultraviolet generators mounted on the ceiling equidistant from the ends of the room. As a test of the antiseptic efficiency of these generators the rate of atmospheric sterilization was first determined quantitatively. Ten sterile Petri dishes containing potato-dextrose agar were placed on small tables in various parts of the room. Each dish was opened for three minutes and then incubated. In control tests before turning on the generators, 151 colonies developed on the ten exposed plates. The room was retested by the same technic after one, two, three, four and five hours' ultraviolet irradiation. By the end of one hour the number of viable air contaminants had been reduced to 116 on ten plates, a 23 per cent reduction in the initial count. There was a further reduction to 97 colonies by the end of two hours' and to 13 colonies after three hours' irradiation. Only 1 colony developed on the ten plates after four hours' irradiation, a 99.33 per cent reduction in the original number of viable air contaminants. The room has been used for several weeks for the routine preparation of grain spawn, each day's use being preceded by four hours' ultraviolet sterilization. To date the average spoilage in the ultraviolet sterilized room has been about one bottle per set, a 95 per cent

reduction in the previous economic loss. Kligman believes that this method of room sterilization has numerous other applications in industrial plants and in clinical laboratories.

OCCUPATIONAL DISEASES AND THE INDUSTRIAL ACCIDENT COMMISSION OF MARYLAND

In spite of innumerable surveys and investigations, little reliable information is available about many important professional relationships in the administration of workmen's compensation. The published reports available are insufficient to permit a thoroughgoing evaluation of official medical boards which act as advisers to administrators on controversial medical issues. The situation is clarified through the appearance of an annual report by the Medical Board for Occupational Diseases of the Maryland Industrial Accident Commission,¹ purported to be the first document of its kind in this country. This report is unlike the conventional statements issued by compensation boards, since it does not confine itself to statistical analyses but presents also in abstract of all claims heard, the medical issues involved, the observations of the Medical Board and the final opinion by the Workmen's Compensation Commission itself. There have not been reversals of decisions of the Medical Board. The procedure outlined in this report, or such modification as would fit special circumstances, will seem to physicians most enlightened and sensible. This is particularly true if the weight of medical opinion cannot be arbitrarily set aside and if the character of appointment and tenure of office are nonpolitical. In any event these abstracted case reports and the opinions of the Medical Board will provide students of compensation and the medical profession at large with factual data which can be widely regarded as dependable medical opinion on the ability of occupation to cause or contribute to abnormal or disease states.

FIFTY YEARS A MEDICAL LIBRARIAN

Mr. James F. Ballard, director of the Boston Medical Library, completed fifty years of service to that institution on October 23. Formerly he was president of the Medical Library Association, and his classification of books is used in almost every medical library in this country. His advice has been sought in the past by the Rockefeller Foundation and by the General Education Board in establishing medical libraries in this country and abroad. One of his chief interests has been fifteenth century books. The trustees have proposed to the fellows and friends of the Boston Medical Library the immediate accumulation of a fund to be known as the James F. Ballard Publication Fund in recognition of his half century of continuous efficient and unselfish service. The first issue, now in press, about which an announcement will soon be made, will be "A Catalogue of Mediaeval and Renaissance Manuscripts and Incunabula in the Boston Medical Library," compiled by Mr. Ballard under the direction of the librarian, Dr. Viets.

¹ First Annual Report of the Medical Board for Occupational Diseases, Maryland Industrial Accident Commission for the Period June 1, 1939 to Oct. 31, 1940 Inclusive.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

NEW NAVY HOSPITAL IN PANAMA

A new hospital at a navy station in the Panama Canal zone was recently dedicated and is now under command of Capt C W Ross, with Capt M L Marquette as the executive. At the dedication, speeches were made by Capt D E Cummings, chief of staff of the Fifteenth Naval District, and by Comdr Edward D Garfin, officer in charge of constructing the hospital. A second navy hospital in this area is now under construction. With the completion of this new hospital, navy men will be treated by their own officers instead of depending to some extent on army hospital facilities in the Panama Canal.

MEDICAL OFFICERS AWARDED THE PURPLE HEART

The American Army Forces in China, Burma and India announce the award of the Purple Heart to Col Robert P Williams, M C, Major Gordon S Scgrave, M C, Major Donald M O'Hara, D C, and Capt John H Grindlay, M C. The citation of Colonel Williams was "For singularly meritorious and essential service in Burma between 15 March 1942 and 1 May 1942. By thorough, painstaking and untiring effort Colonel Williams assisted the Chinese Fifth Army in the organization and maintenance of its medical service, without which the usefulness of that army would have been greatly reduced. This outstanding service reflects great credit on the military forces of the United States."

Major Scgrave, Major O'Hara and Captain Grindlay were thus cited "For singularly meritorious service in Burma between 15 March 1942 and 1 May 1942. By the maintenance of a surgical service close to the front, under frequent bombing, working for long hours with meager and improvised equipment, [he] rendered a service to the Chinese Fifth Army which resulted in the saving of many Chinese lives. This outstanding service reflects great credit on the military forces of the United States."

APPOINTMENTS BY OFFICE OF CIVILIAN DEFENSE

Dr Ward L Mould of the Office of Civilian Defense, Washington, D C, has been appointed medical adviser to industrial plants to assist in planning for adequate medical services in the event of a major emergency and will cooperate with the Emergency Medical Service organized in communities. —Dr W Roderick Brown of Pittsburgh has been appointed to the staff of the Office of Civilian Defense in Washington, D C, to supervise the training of Negro physicians in Emergency Medical Service for Civilian Defense. Dr Brown will carry out his program for the present through the postgraduate institutes for physicians sponsored by the National Tuberculosis Association. These institutes will be held in Arkansas, California, Florida, Indiana, Kentucky, Louisiana, Mississippi, Maryland, Ohio, Pennsylvania, South Carolina, Tennessee, Texas, Virginia and the District of Columbia. Dr Brown is a graduate of Howard University College of Medicine, Washington, D C, and for several years has been a member of the staff of the chest unit of the University of Pittsburgh Medical Center and visiting physician to the Pittsburgh City Tuberculosis Hospital. —Dr Karl J Thomson, associate director of the Metropolitan Life Insurance Company Sanatorium, Mount McGregor, N Y, has joined the Washington staff of the Office of Civilian Defense. He is a graduate of Harvard Medical School and has carried on research at Harvard and at Albany Medical College.

RED CROSS BLOOD DONOR SERVICE

The American Red Cross Blood Donor Service was recently selected to receive the Army-Navy Production Award for its work in procuring blood for dried plasma for the armed forces. The eighteen blood donor centers located throughout the country will therefore have the right to fly the Army-Navy Production Award Pennant, and all employees will be privileged to wear special Army-Navy E pins. In February 1941 the Surgeon Generals of the Army and Navy requested the American Red Cross to set up a center to procure blood for 15,000 units of dried plasma for emergency transfusions. Three months later the amount requested was increased to 215,000 units and following the attack on Pearl Harbor the request was made for 165,000 additional units of dried plasma, making a total of 380,000 units for delivery by July 1, and this amount was exceeded three weeks ahead of schedule. The American Red Cross will continue to expand its blood collecting facilities as rapidly as laboratory arrangements can be made to process the blood into dried plasma and into serum albumin, a more recently developed blood substitute.

CORRECTION—PUBLIC HEALTH NURSES NEEDED

The U S Civil Service Commission recently issued a call to public health nurses. The commission desires now to correct the statement made regarding the omission of high school education as a requirement for public health nurse positions. This statement was made in error by the commission. The educational requirements for public health nurse cannot be obtained without completion of a high school education.

The requirements are completion, subsequent to Jan 1, 1920, of a full course in a recognized school of nursing including two years in a general hospital having a daily average of 50 bed patients or more, registration as a graduate nurse and completion of one year of study in public health nursing at a college giving a course of study approved by the National Organization for Public Health Nursing. One year of public health nursing experience also is necessary. The public health nurse positions pay \$2,000 a year.

Other nursing opportunities open in the federal service are junior public health nurse, \$1,800 a year, graduate nurse, \$1,800 a year, junior graduate nurse, \$1,620, graduate nurse for the Panama Canal service, \$168.75 a month, nursing education consultant, \$2,600 to \$4,600 a year, and public health nursing consultant, \$2,600 to \$5,600 a year.

Except for Panama Canal service there are no age limits for any of these positions. Applications will be accepted at the commission's office in Washington, D C, until the needs of the service have been met.

SPECIAL TRAINING COURSE AT FIELD SERVICE SCHOOL

Fifty-four officers of the medical department of the army completed training at the Medical Field Service School, Carlisle Barracks, Pa, October 3, for assignments in medical battalions of new infantry divisions now being activated. These officers came from twenty different states and twenty-three of them were captains, nineteen first lieutenants, ten majors and two second lieutenants. All of them held commissions in the medical corps except five, who were commissioned in the medical administrative corps. A new class took up this course of instruction on October 3.

ORGANIZATION SECTION

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status—S 2412 has been ordered favorably reported by the House Committee on the Judiciary, a bill to provide benefits, including medical care, for the injury, disability or death of civilians or their detention by the enemy and for the prevention and relief of civilian distress arising out of the present war.

H R 7568 has been reported to the House, with amendments, a bill to discharge more effectively the obligations of the United States under certain treaties relating to the manufacture and distribution of narcotic drugs by providing for domestic control

of the production and distribution of the opium poppy and its products.

Bills Introduced—S 2834, introduced by Senator Clark, Missouri, a bill to define the term misconduct as used in veterans' regulations providing for compensation and pension so as to limit the meaning of the term to felonious misconduct. S 2846, introduced by Senator Reynolds, North Carolina, and H R 7703, introduced by Representative Shafer, Michigan, propose to amend the Railroad Retirement Act of 1937 so as to provide disability benefits after completion of a specified term of service.

OFFICIAL NOTES

ABSTRACT OF MINUTES OF MEETINGS OF BOARD OF TRUSTEES, SEPT 17 AND 18, 1942

A two day session of the Board of Trustees was held at the headquarters of the Association September 17 and 18 preceded by a full day meeting of the Executive Committee. Some of the matters acted on are reported here, others will be discussed at later meetings.

APPOINTMENTS

The following appointments were made: Dr L H Bauer, Hempstead, N Y, to represent the American Medical Association at the Conference on Rehabilitation, called by the American Physiotherapy Association.

Dr Charles W Roberts of Atlanta, Ga., to the Advisory Committee of the Woman's Auxiliary to succeed Dr Arthur W Booth.

Dr W W Bauer, Director of the Bureau of Health Education, Dr John S Coulter of Chicago, Dr Peter J Stemmerhuf of Hartford, Conn and Dr H A Christian of Brookline, Mass., on a committee established by the American Association for Health, Physical Education and Recreation for the purpose of endeavoring to frame a simple definition and statement for the use of health educators on the value, dangers and limitations of exercise.

Dr Charles W Roberts to succeed Dr Roger I Lee on the Committee on Scientific Exhibits. Dr Elmer L Henderson, Chairman of the Committee.

Dr Glenville Giddings of Atlanta, Ga., on the Agricultural and Industrial Relations Committee of the Southern Regional Research Laboratory.

Mr George E Hall of the Bureau of Legal Medicine and Legislation on a special committee of the National Research Council having to do with tests for intoxication.

Dr George H Whipple of Rochester, N Y, was elected as a member and as chairman of the Committee for the Protection of Medical Research to succeed Dr Elliott C Cutler, who resigned on going into active service in the Army.

RADIO BROADCASTS

The Board approved cooperation of the Bureau of Health Education with the Blue Network in a weekly daytime series of interviews with prominent physicians. Announcements will be made in *THE JOURNAL* when these programs begin.

SPANISH AND PORTUGUESE PERIODICALS

The Board approved the publication of monthly periodicals in Spanish and Portuguese.

RESIGNATION OF MAJOR W P HOLBROOK FROM THE COMMITTEE ON AMERICAN HEALTH RESORTS

The resignation of Major W P Holbrook from the Committee on American Health Resorts, because his duties in the

Army make it impossible for him to fulfil his share of the obligations of the committee, was accepted.

FELLOWSHIP FOR STUDY OF PREPARED BREAKFAST CEREAL FOODS

The Board created a special fund of \$1,000 for the Council on Foods and Nutrition for the establishment of a fellowship for the study of the composition of a large number of prepared breakfast cereal foods and the grains from which they are made.

STUDY OF HOSPITAL CORPORATIONS ENGAGING IN PRACTICE OF MEDICINE AND OF RELATION BETWEEN PHYSICIANS AND INSURANCE COMPANIES

A committee of three was appointed to study the matter of hospital corporations engaging in the practice of medicine and of the improvement of relations between physicians and insurance companies.

TERMS OF SERVICE OF MEMBERS OF THE COUNCIL ON INDUSTRIAL HEALTH

The Board rescinded action previously taken establishing the tenure of service of members of the Council on Industrial Health as five years and took action establishing these terms as four years. The terms of the present members of the Council will be revised at the annual meeting of the Board in February.

MEETINGS WITH REPRESENTATIVES OF THE HOSPITAL ASSOCIATIONS

The Board authorized arrangements for a meeting with representatives of national hospital associations during its meeting in November for the consideration of medical service and prepayment hospitalization plans.

COOPERATION BETWEEN AMERICAN MEDICAL ASSOCIATION AND AMERICAN PHARMACEUTICAL ASSOCIATION

Authorization was given for the continuation of joint conferences between the American Medical Association and the American Pharmaceutical Association with a view to establishing more cooperative relations between the two organizations.

MEDICAL AND DENTAL CARE OF CIVILIAN COMMUNITIES

The Board, which had previously voted by mail, approved the tentative plan for medical and dental care of civilian communities adopted by the War Participation Committee of the American Medical Association.

COMMITTEE ON STUDENT HEALTH

The Board authorized the establishment of a committee of five to be concerned with the problems and policies relating to student health.

PROVISIONS FOR CIVILIANS FOR MEDICAL CARE AND HOSPITALIZATION NECESSITATED BY ENEMY ACTION

Approval was given for the organization of hospital units in the United States Public Health Service to be called into action in time of enemy action in emergencies only and for no other purpose.

REFURBISHING OF HEADQUARTERS BUILDING

Authorization was given by the Board for the refurbishing of the interior of the headquarters building, which has not been decorated since the addition of the two stories in 1936.

WAR MEDICINE

Authorization was given for publishing *War Medicine* on a monthly basis as soon as expedient.

MEDICAL EXHIBITS FOR MEDICAL SOCIETIES AND SCIENTIFIC ORGANIZATIONS

Exhibits pertaining to the work of the various departments of the American Medical Association and to subjects in which those departments are interested have been prepared for medical societies and other scientific organizations. The exhibits are available on a loan basis. Responsibility for installation and demonstration of the exhibits ordinarily must be borne by the organization to which the material is lent. Only in special instances will the American Medical Association be able to send its own personnel for such duties. Requests for material should be instituted as far in advance as possible, so that the proper reservations can be made. Exact shipping addresses and dates should be given when the request is made. Further information may be obtained from Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago.

16 Heroes of Medicine An exhibit, originally shown at the Golden Gate International Exposition in San Francisco, consisting of ten groups of figures—McDowell, Beaumont, Long, Holmes, Sims, Welch, Gorgas, Theobald Smith, Ricketts and Reed. Each group is set in a case with indirect lighting. Models are made of rubber and are quite substantial. Space required, area 10 feet wide by 10 feet deep (or 21 linear feet). Electrical connections, ten outlets using a total of 400 watts. Shipping weight, 933 pounds.

31 Hospital Service in the United States An exhibit from the Council on Medical Education and Hospitals presenting data on hospitals collected in the annual survey, miscellaneous posters and pamphlets. Space required, one or two booths according to material selected, together with tables for literature. Shipping weight, according to material selected.

34 Tularemia (spread and control) An exhibit from the Scientific Exhibit of the American Medical Association made in conjunction with Dr. Walter M. Simpson, Miami Valley Hospital, Dayton, Ohio, and Dr. Edward Francis, U. S. Public Health Service, Washington, D. C., consisting of transparencies showing clinical cases of tularemia and posters on panels showing the prevalence, animal hosts, insect vectors and what to do to prevent infection. An exposition "microscope" shows the tularemia organism. Space required, an area 10 feet wide by 6 feet deep, no background necessary. Electrical connections, two outlets for lamps in transparency case and exposition "microscope" using 255 watts. Shipping weight, 297 pounds.

35 Tularemia (pathology) An exhibit from the Scientific Exhibit of the American Medical Association of photographs, photomicrographs and roentgenograms collected by Dr. Walter M. Simpson and Dr. Edward Francis, showing the pathologic changes of tularemia in animals and man. Space required, an area 10 feet wide by 6 feet deep, no background necessary. Electrical connections, one outlet for lamps in transparency case using 240 watts. Shipping weight, 260 pounds.

42 'Patent Medicine' Testimonials An exhibit from the Bureau of Investigation consisting of posters showing testimonials for 'patent medicines' with the death notice of the person in the same copy of the newspaper or the death certificate dated some weeks or months previously. Two visitor

participation units, one with a transparent mirror showing appropriate cartoon and one with questions and answers. Space required, a booth with back wall 10 feet wide and side walls 6 feet deep for twelve posters each 24 by 30 inches, two small tables for transparent mirror and question and answer device. Electrical connections, two outlets alternating current, using about 150 watts. Shipping weight, 275 pounds.

44 Cancer Death Certificates An exhibit from the Bureau of Investigation in conjunction with the Texas State Board of Medical Examiners, presenting some two hundred cancer death certificates from an advertising 'cancer' hospital. Space required, an area 10 feet wide by 6 feet deep, no background necessary. Electrical connections, none. Shipping weight, 253 pounds.

46 Food Fads An exhibit from the Bureau of Investigation consisting of a mechanical attention arrester, two sets of transparencies showing persons whose diet requires special attention and persons whose diet should have been more carefully regulated, six posters each 22 by 38 inches dealing with some of the popular, but foolish, food fads, an exposition file with additional information. Space required, a booth with back wall 10 feet wide and side walls each 6 feet deep, three small tables for transparencies and exposition file. Electrical connections, three outlets for transparency cases and small universal motor totaling about 600 watts. Shipping weight, 389 pounds.

47 Mechanical Nostrums An exhibit from the Council on Physical Therapy and the Bureau of Investigation showing various mechanical devices, such as the 'horse collar' and the 'gas pipe' cure for which weird claims have been made, together with an exposition file containing descriptions of many more similar gadgets. Space required, an area 10 feet wide for a table, with wall space above for 8 panels each 22 by 28 inches. Electrical connections, none. Shipping weight, 330 pounds.

48 Chemistry of Vitamin K and Synthetic Hormones An exhibit from the A. M. A. Chemical Laboratory consisting of nine charts in frames 24 by 30 inches, showing vitamin K active compounds, the role of vitamin K in blood clotting and rationale of vitamin K therapy, together with photomicrographs. Similar information is given for the synthetic hormones. Space required, background 8 feet wide, with side walls 2 feet deep (or without side walls a background of 12 feet). Electrical connections, none. Shipping weight, 74 pounds.

50 Use and Abuse of Barbiturates An exhibit from the Council on Pharmacy and Chemistry consisting of posters showing the use and abuse of the barbiturates, a chart giving the names and chemical formulas of thirty products on the market, an exposition file and New and Nonofficial Remedies giving additional information. Space required, a booth with back wall 10 feet wide and side walls 6 feet deep on which to hang charts and posters, a table for exposition file and N. N. R. and question box. Shipping weight, 143 pounds.

51 Chemistry of the Gastric Antacids An exhibit from the A. M. A. Chemical Laboratory consisting of five posters in frames, each 24 by 30 inches, presenting information on the ideal gastric antacid, comparison of gastric antacids, their combining powers, reaction rates and rebound secretions. Space required, a background 10 feet wide. Electrical connections, none. Shipping weight, about 60 pounds.

52 Chemistry of the Sulfonamide Drugs An exhibit from the A. M. A. Chemical Laboratory consisting of a transparency showing crystals of the sulfonamide drugs in color together with six posters, each 24 by 30 inches in size, dealing with the chemistry of the subject. Space required, an area 10 feet wide with a background for posters. Electrical connections, one outlet for transparency case using 180 watts. Shipping weight, 141 pounds.

53 Nutritionally Improved Flour An exhibit from the Council on Foods and Nutrition consisting of samples of wheat and flour showing the amount of vitamin B₁ in various milling products, ten posters, each 24 by 30 inches in size, dealing with further aspects of the subject, reprints and pamphlets together with a question box. Space required, an area 10 feet wide by 6 feet deep, with back wall and side walls for posters (or with no side walls but a back wall 20 feet wide) table for racks and literature, 8 feet long. Shipping weight, 233 pounds.

54 Work of the Council on Physical Therapy An exhibit from the Council on Physical Therapy consisting of miscellaneous charts in frames, each 24 by 30 inches, together with selected apparatus. The following groups have been found of interest: short wave diathermy, simple apparatus for physical therapy, miscellaneous posters dealing with the work of the Council. Space required, variable according to kind of material selected. Electrical connections: one or more outlets if mechanical material is selected. Shipping weight, variable according to material selected.

55 Posture An exhibit from the Council on Physical Therapy consisting of a manikin for visitor participation showing correct and incorrect posture, transparencies showing reasons for good posture and panels with posters showing the relation of sitting and posture, the feet and posture, the causes of poor posture and recommendations for good posture. An exposition file gives additional information. Space required: an area 10 feet wide by 6 feet deep, no background necessary; two small tables, one for manikin and one for exposition file. Electrical connections: three outlets for lamps in cases using a total of 440 watts. Shipping weight, 400 pounds.

56 Audiometers and Hearing Aids An exhibit from the Council on Physical Therapy consisting of apparatus and charts accompanied by demonstrations and lectures on the physics of audiometers and hearing aids, also instruction on the calculation of percentage loss of hearing. Space required: a booth 15 feet wide and 10 feet deep with a background for charts. Electrical connections, outlet for 1,000 watts. Shipping weight, variable according to amount of material selected.

57 Amputations An exhibit from the Council on Physical Therapy consisting of six manikins showing most suitable sites for leg amputations, and charts in frames 24 by 30 inches showing sites for finger amputations, question box and two literature racks. Space required: a booth 12 feet wide and 10 feet deep with a background for charts, one table for racks. Electrical connections, none. Shipping weight, about 800 pounds.

58 Dietary Deficiency Diseases An exhibit from the Council on Foods and Nutrition of the American Medical Association in conjunction with the Food and Nutrition Board of the National Research Council. There are three transparency cases showing pictures of the results of food deficiencies and eight panels with charts showing the values of various foods, together with a question box and an exposition file giving additional information. Space required: an area 20 feet wide by 6 feet deep, no background necessary; four tables each 4 feet long, for transparency cases and files. Electrical connections, three outlets using 1,200 watts. Shipping weight, 640 pounds.

63 Industrial Health An exhibit from the Council on Industrial Health consisting of a group of posters showing the status of industrial health in the United States. Space required, a booth with back wall 10 feet wide and side walls on which to hang posters. Shipping weight, 125 pounds.

65 Industrial Health Program for a County Medical Society An exhibit from the Council on Industrial Health consisting of posters on panels, showing the organization and activities of an industrial health program for a county medical society. Space required, an area about 10 feet wide by 6 feet deep, no background necessary. Electrical connections, none. Shipping weight, 200 pounds.

66 Basic Science Laws An exhibit from the Bureau of Legal Medicine and Legislation consisting of six charts and frames, each 24 by 30 inches, together with a shadow box. Space required, a booth with back wall 10 feet wide, and side walls 6 feet deep (15 linear feet). Electrical connections, one outlet, 120 watts. Shipping weight, 154 pounds.

69 Health Education in the Doctor's Office An exhibit from the Bureau of Health Education consisting of posters on panels showing educational possibilities of the doctor's waiting room, consultation room, treatment room and the doctor's community contacts. Display racks contain samples of literature dealing with *Hygeia* loan collections, radio talks, pamphlets, posters, bibliographies, and so on. Space required, an area about 10 feet wide by 6 feet deep, one small table for question box, no background necessary. Electrical connections, two outlets for display racks requiring a total of 240 watts. Shipping weight, 500 pounds.

70 Cutaneous Manifestations of Tuberculosis An exhibit from the Scientific Exhibit of the American Medical Association, in conjunction with the Section on Dermatology and Syphilology, consisting of four panels each 5 feet high and 3 feet wide, showing photographs of cutaneous tuberculosis and conditions which simulate it. Space required, an area 10 feet wide by 3 feet deep, no background necessary. Shipping weight, 166 pounds.

71 Cutaneous Granulomas An exhibit from the Scientific Exhibit of the American Medical Association, in conjunction with the Section on Dermatology and Syphilology, consisting of photographs of various granulomas (other than tuberculosis and syphilis) including one panel of leprosy and one panel of drugs. The photographs are mounted on six panels, each 5 feet high and 3 feet wide, with legs $2\frac{1}{2}$ feet high which can be installed readily. Space required: an area 12 feet wide by 3 feet deep, no background necessary. Shipping weight, 250 pounds.

72 Cutaneous Manifestations of Syphilis An exhibit from the Scientific Exhibit of the American Medical Association, in conjunction with the Section on Dermatology and Syphilology, consisting of about one hundred and fifty photographs of the various syphilitic lesions in different stages of the disease. The photographs are mounted on panels 5 feet high by 3 feet wide, with legs $2\frac{1}{2}$ feet high which can be installed readily. Space required: an area 15 feet wide by 3 feet deep, no background necessary. Shipping weight, 327 pounds.

74 Experimental Uterine and Extragenital Fibroids Induced by Estrogens An exhibit originally shown by Dr. Alexander Lipschutz, Department of Experimental Medicine, National Health Service, Santiago, Chile, in the Scientific Exhibit of the American Medical Association. It consists of twenty-nine photographs mounted on boards for easy installation. Space required: a back wall 10 feet wide. Electrical connections, none. Shipping weight, 90 pounds.

78 Aesculapian Hygeia, Hippocrates and Osler Four plaster plaques in bas-relief from the Bureau of Exhibits. Each figure is $8\frac{1}{2}$ feet high, 3 feet wide and 6 inches thick. Because of the fragile nature of the plaques they will be sent only where they can be suitably installed. Shipping weight: Aesculapian 343 pounds, Hygeia 354 pounds, Hippocrates 300 pounds and Osler 366 pounds.

81 Pneumococcosis An exhibit prepared for the Council on Industrial Health by the Sarrac Laboratory, consisting of transparencies and posters on panels dealing with various phases of pneumococcosis. Space required: an area 9 feet wide by 15 inches deep, no background necessary. Electrical connections: one outlet for transparency case, using 360 watts. Shipping weight, 205 pounds.

82 Asbestosis An exhibit prepared for the Council on Industrial Health by the Sarrac Laboratory, consisting of transparencies and posters on panels dealing with various phases of asbestosis. Space required, an area 9 feet wide by 15 inches deep, no background necessary. Electrical connections: one outlet for transparency case using 360 watts. Shipping weight, 204 pounds.

83 Tuberculosis An exhibit prepared for the Council on Industrial Health by the Sarrac Laboratory, consisting of transparencies and posters on panels, dealing with various phases of tuberculosis as it is related to the problem of silicosis. Space required: an area 9 feet wide by 15 inches deep, no background necessary. Electrical connections: one outlet for transparency case, using 360 watts. Shipping weight, 204 pounds.

84 Silicosis An exhibit prepared for the Council on Industrial Health by the Sarrac Laboratory, consisting of two transparency cases and three sets of posters on panels, dealing with various phases of silicosis. Space required: an area 15 feet wide by 15 inches deep, no background necessary. Electrical connections, two outlets for transparency cases, using 720 watts. Shipping weight, 363 pounds.

93 Hygeia the Health Magazine An exhibit consisting of an enlarged photograph of a small boy, together with two shadow boxes containing information about *Hygeia*, sample copies and other literature for distribution. Space required, an area 10 feet wide by 6 feet deep. Electrical connections, two outlets for shadow boxes 120 watts. Shipping weight, about 300 pounds with literature.

CALIFORNIA

New Professor of Obstetrics—Dr Herbert F Traut associate professor of obstetrics and gynecology at Cornell University Medical College New York has been appointed professor of gynecology and obstetrics at the University of California Medical School San Francisco Dr Traut graduated at Johns Hopkins University School of Medicine Baltimore, in 1923, he has been associate professor at Cornell since 1931

Annual Symposium on Cardiovascular Disease—The Los Angeles Heart Association will hold its twelfth annual symposium at the Los Angeles County Hospital and the Los Angeles County Medical Association November 12-13 On Thursday evening, at a joint dinner meeting with the Southwestern Pediatric Society, Dr Louis E Martin Los Angeles will deliver his presidential address and Dr Thomas Duckett Jones Boston, will discuss 'Rheumatic Fever and Rheumatic Heart Disease' Among the speakers on the program will be

Dr B Eugene Levine Los Angeles The Heart and Circulation in Diphtheria

Dr John W Askey Los Angeles The General Practitioner and His Choice of a Digitalis Preparation

Dr Morris H Nathanson Los Angeles Practical Use of Adrenalin and Related Compounds in Cardiovascular Disease

Drs Hugh A Edmondson and Harold J Hovie Los Angeles Rupture and Other Complications of Myocardial Infarction

Dr Clara Margoles Los Angeles Collateral Circulation in the Human Heart

Dr Meinerd Brandsmas Beverly Hills New Methods in the Treatment of Bacterial Endocarditis

DISTRICT OF COLUMBIA

Shorter Hospital Period After Child Birth—A plan has been placed in effect in Washington hospitals whereby mothers are being urged to shorten their stay at hospitals following child birth, newspapers reported October 10 The increased number of obstetric cases which have crowded Washington hospitals already overburdened by the wartime increase in population, has reached such proportions that hospitals are urging mothers to return home with their newborn babies, sometimes within one day after birth to vacate beds for more cases it was stated The plan when thoroughly working throughout the city, probably will increase the maternity facilities by 20 to 25 per cent Live births have been on the increase since 1935 when they totaled 10,803 In 1940 there were 15,309 and in 1941 18,294 There were 6,582 births in the first four months of 1942

ILLINOIS

Illinois Health Conference in St Louis—Dr Edward S Godfrey Jr, New York State commissioner of health, Albany, will speak at the dinner of the Illinois Public Health Association at the New Jefferson Hotel St Louis, October 26 on 'Public Health in Illinois a Generation Ago' The speakers at the conference on public health at the Municipal Auditorium in the afternoon will be Dr Roland R Cross Springfield health officer of Illinois, Dr Mark V Ziegler Chicago, Local Public Health Administration Frederic C Woodward LL D, Chicago, 'Illinois Statewide Public Health Committee' Clair E Turner, Dr PH, Boston 'Mobilizing Local Leadership for Public Health,' and Dr Huntington Williams, Baltimore Blitz Medical Services in England and What They Teach Us The meeting of the Illinois group is a feature of the annual session of the American Public Health Association

Chicago

Course in Industrial Medicine—Loyola University School of Medicine is offering a course to meet the practical needs of the nurses employed in industry The U S Public Health Service is financing the course which will consist of twelve lectures beginning November 2 and ending January 25 covering orientation in industrial health records and their use compensation laws, problems of women in industry, use of community resources, diet and nutrition mental hygiene first aid, safety programs in industry, major causes of illness, control program and the evaluation of the industrial health program

Research in Brief Psychotherapy—The first research meeting of the newly formed Council for Research in Brief Psychotherapy will be held at the Institute for Psychoanalysis in Chicago, October 25-26 The types of cases treated techniques employed therapeutic results and recording research material on brief psychotherapy will be the theme of discussions The council was formed at a meeting in Boston in May under the auspices of the Institute for Psychoanalysis Members of the committee of the council are Drs Franz G Alexander chairman Arthur H Ruggles, Providence R I Robert P Knight, Topeka, Kan George E Daniels New York Francis J Gerty Chicago Fanny von Hann Kende New York John C Whitehorn Baltimore David M Levy, New York David Slight Chicago Nolan D C Lewis New York Major Roy R Grinker and members of the staff of the Institute for Psychoanalysis

Institute on War Medicine for Dentists—The Chicago Dental Society will present an institute of war medicine and surgery for dentists at the John B Murphy Memorial Hall October 26-29 Among the speakers will be

Lieut Walter A Machun U S Army The Feeding of the American Soldier

Clay G Huff Sc D Chicago Tropical Medicine

Dr Harry A Oberhelman Chicago The Principles of Traumatic Surgery

Major W H Weir U S Army Boston Military Sanitation

Dr Walter Wilkins Washington D C Nutrition in Wartime

Lieut D D Jackson D C U S Navy The Experience of a Dental Officer on the U S S Yorktown

J Ben Robinson DDS Baltimore The Role of the Dental Profession in the War Effort

Perceval C Lowery DDS Detroit The Use of Acrylics in the Construction of Splints and in Maxillofacial Prosthetics

Arthur H Bulbulian DDS Rochester Minn Facial Reconstruction

Glenn E Willhelmy DDS Kansas City Aviation Splints

John Jacob Posner DDS New York Local Anesthesia Under War Conditions

W Harry Archer DDS Pittsburgh General Anesthesia Under War Conditions

Kurt H Thoma DMD Boston Traumatic Surgery of the Jaws

KENTUCKY

Changes in Health Officers—Dr Martin H Skaggs Taylorsville was recently elected health officer of Shelby County September 8 The county health unit was opened officially on July 1—Dr Theodore E Hynson formerly of Dover, Del has been appointed health officer of Harlan County

Society News—Dr Oscar E Bloch Jr, Louisville delivered an essay entitled Water Balance in Disease before the Louisville Society of Medicine recently—Dr Andre Crotti Columbus addressed the Jefferson County Medical Society in Louisville, October 19 and showed a motion picture on 'Physiologic Reactions in Operations of the Abdomen Chest and Brain'—The Louisville Society of Medicine was addressed October 1 by Dr John P Forsee Louisville on 'Chronic Fatigue'

State Medical Election—Dr Caswell C Turner Glasgow was chosen president-elect of the Kentucky State Medical Association at its annual meeting in Louisville October 1 and Dr E Murphy Howard Harlan, was inducted into the presidency Vice presidents are Drs Oscar O Miller Louisville Charles L Sherman Millwood, and D Hunter Coleman Harrodsburg Dr Ben Wilson Smock Louisville was chosen to give the oration in surgery in 1943 and Dr Charles B Stacy Pineville the oration in medicine

LOUISIANA

Tropical Medicine at Tulane—Twelve Latin American physicians started the course in tropical medicine at Tulane University of Louisiana School of Medicine, New Orleans in September under fellowships financed by the American Foundation for Tropical Medicine They are Drs M Sanchez Basseres, Brazil M A Cardenas Chile Benjamin Mera, Colombia Alejandro Gonzalez L Costa Rica Gilberto Gomez R Dominican Republic Alfonso Marchan Ecuador Jose Pacas M El Salvador Jose Bustos Mexico Silvestre Lopez Portillo Mexico Carlos Calera M Panama Jorge Clavier Venezuela, and Tulio Briceno, Venezuela Dr L Everard Napier director of the Calcutta School of Tropical Medicine and editor of the *Indian Medical Gazette* recently accepted a visiting professorship in the department of tropical medicine and is expected to join the staff early in 1943 During the past spring and early summer the staff of the department of tropical medicine gave intensive night courses in tropical medicine to physicians in the military forces stationed in New Orleans Ernest C Faust Ph D head of the division and director of laboratories of tropical medicine at Tulane and consultant to the Secretary of War on tropical diseases and on epidemic diseases lectures every two months at the Army Medical School,

Washington Drs Faust and Joseph S D'Antoni, assistant professor of the department, are collaborating with the division of medical sciences of the National Research Council in lecturing on tropical medicine at medical schools in the East and North during October and November. In 1941 the General Education Board of the Rockefeller Foundation gave \$200,000 to enlarge the personnel of the department and to plan for a more permanent teaching program for undergraduate and postgraduate work in the field. Since 1940 the American Foundation for Tropical Medicine has provided an annual sum of \$9,000 for postgraduate teaching particularly for a special intensive course for Latin American physicians. This year two fellowship grants have been made available for the North American physicians by the Lambert Pharmaceutical Company, St. Louis, and the Winthrop Chemical Company, New York. Since 1940 the Eli Lilly Company has provided a yearly grant of \$5,000 for unrestricted research carried out under the auspices of the department. Under the program the physician receives intensive training both in laboratory and in clinical tropical medicine in addition to review work in the general field of medicine, additional training is provided by special guest lecturers who are experts in their respective fields.

MARYLAND

Chest Clinics—The state department of health announces its regular series of chest clinics for the fall and winter of 1942 and 1943. The clinics are conducted under the joint auspices of the state health department and the state tuberculosis association and are made possible through the sale of Christmas seals. In 1941 there were 352 clinics attended by more than 7,000 patients, 500 of whom were admitted to the tuberculosis sanatorium for treatment. The clinics reached every section of the counties at least once. The patients were referred by their own physicians or were discovered by the county health officers and public health nurses in connection with various other services. In connection with the clinic services public health nurses paid more than 11,000 visits to the homes of the patients in 1941.

Bacteriologic Seminars—The weekly bacteriologic seminars arranged by the bureau of bacteriology of the state department of health for the review of current literature, discussion of laboratory procedure and advances in research were resumed for the season October 1 with a talk by John Brewer, Ph.D., Baltimore, on "Problems Involved in the Sterilization of Sulfonamides." Dr. Milton S. Sacks, Baltimore, spoke October 15 on "Relationship of the Rh Factor to Intro Group Hemolytic Transfusion Reactions and Pathogenesis of Erythroblastosis Foetalis." Others in the series will be

Thomas C. Grubb, Ph.D., Baltimore, The Electron Microscope, November 5.
Ethelinda Brower, A.B., Baltimore, Immune Response to Tetanus Toxoid, November 19.
Dr. Thomas B. Turner, Baltimore, How Can the Laboratory Cooperate in the War Effort, December 3.
Justina H. Hill, D.Sc., Baltimore, Gonococcus Culture Methods, December 17.
Dr. John J. Phair, Baltimore, Epidemic Meningitis, January 17.
Harriette D. Vera, Ph.D., Baltimore, Demonstration of Hemolysis Due to Anaerobes, January 20.

These seminars were started in 1936 and have been continued each season since then as a part of the regular education program of the bureau of bacteriology.

MICHIGAN

Lectures on Nutrition—A series of lectures on nutrition in medicine, dentistry and industry has been arranged by the Wayne County Medical Society, Detroit District Dental Society, Detroit Physiological Society, Detroit Pediatric Society and the Engineering Society of Detroit. The first in the group was given on October 12 by Dr. Tom D. Spies, Cincinnati, Ohio, and Birmingham, Ala., on "Recent Advances in Vitamin Research." Subsequent lectures will be

Dr. Ewing C. McBeath, New York, October 29, Nutrition and Dental Health.
Dr. Anton J. Carlson, Chicago, November 19, What's Wrong with America's Diet?
Dr. Frederick F. Tisdall, Toronto, December 14, Nutrition in Everyday Practice.
Dr. Robert S. Goodhart, Forest Hills, N.Y., January 15, Importance of Nutrition in Prevention of Industrial Injury.

Sponsors of these lectures which emphasize the significance of nutrition in the fields of medicine, dentistry and industry, are the University of Michigan Medical School, Ann Arbor, Wayne University College of Medicine, Wayne County Nutrition Committee and the Children's Fund of Michigan.

NEW YORK

Society News—The Medical Society of the State of New York arranged a lecture on war medicine and surgery for the Cortland County Medical Society in Cortland, October 6. Dr. Leon E. Sutton, Syracuse, was the speaker, his subject was "Healing in Large Deep Burns."

Director of War Nutrition Services—Dr. Edward S. Rogers, Albany, acting assistant commissioner for medical administration of the New York State Department of Health, has been appointed director of the Office of War Nutrition Service of the New York State War Council. He will direct the work of all the departments and agencies of government to the extent that they are concerned with problems related to nutrition. Dr. Alvin A. Florin, Woodmere, assistant district health officer, has been assigned to assist Dr. Rogers full time.

Teaching Day on Chemical Warfare—Syracuse University College of Medicine in cooperation with the health preparedness commission of the State War Council and the state medical society, sponsored a teaching day on medical aspects of chemical warfare in Binghamton, October 15. Dr. Oliver W. H. Mitchell, Syracuse, gave the introductory remarks. Neal L. Artz, Ph.D., Syracuse, discussed "General Aspects and Chemistry" with demonstrations on "Identification of Chemical Agents" and "Use of Gas Mask." Dr. John Howard Ferguson, Syracuse, gave a pathologic demonstration and Drs. Herbert C. Yickel, George S. Reid and David F. Gillette, Syracuse, spoke on "Prevention, Diagnosis and Treatment of Chemical Casualties."

New York City

Annual Harvey Lectures Begin—Vincent du Vigneaud, Ph.D., professor of biochemistry, Cornell University Medical College, will deliver the first Harvey Society Lecture of the current series at the New York Academy of Medicine October 29, on "The Significance of Labile Methyl Groups in the Diet and Their Relation to Transmethylation."

Chest Examination for Nursery Personnel—Of 333 nurseries and nursery schools receiving invitations from the city department of health for free chest examinations, 60 have already replied during the first week of the campaign to detect tuberculosis among the personnel of these nurseries and nursery schools. The campaign was started at this time because it was felt that there was a special need during the war, when an added number of children are being placed in nurseries by mothers taking war jobs.

Tuition Fee Reduced in Course on Industrial Medicine—Long Island College of Medicine, Brooklyn, announces a postgraduate course in industrial medicine, November 2-13. A limited number of internships of one month's duration in medical departments of industrial establishments will be available for those who wish additional training. The fee for the course has been reduced from \$75 to \$50. A special dinner forum will be held November 2 on "Industrial Health and the War Effort." Cyrus S. Ching, director of industrial and public relations, U.S. Rubber Company, will be the speaker.

Dr. Worts Named Littauer Professor of Psychiatry—Dr. Samuel Bernard Worts, associate professor of neurology at the New York University College of Medicine, has been appointed the first Lucius N. Littauer professor of psychiatry and visiting neuropsychiatrist in charge of the psychiatric division of Bellevue Hospital effective October 1. The chair of psychiatry at the medical school has been vacant since the resignation of Dr. Karl M. Bowman to become director of the Langley Porter Clinic in San Francisco. It has now been named the Lucius N. Littauer professorship in honor of the philanthropist who established last year a fund of nearly \$250,000 for research in psychiatry, neurology and related fields, in order to increase and diffuse knowledge of the bio, logical and other factors which influence thought and conduct, and thereby to prevent and correct abnormal human behavior through clinical and experimental approaches. Mr. Littauer had previously given the university nearly \$120,000 for research studies in the prevention and cure of pneumonia, for research studies of venereal disease and for scholarships and fellowships in the college of medicine, Washington Square College of Arts and Sciences, the college of dentistry and other divisions of the university. Dr. Worts graduated at Cornell University Medical College in 1927. He has been a member of the medical faculty of New York University for eleven years.

Institute of Inter-American Affairs—Columbia University and the NBC Inter-American University of the Air sponsored an Institute of Inter-American Affairs October 10-12 on the occasion of the four hundred and fiftieth anniversary of

the discovery of the Americas. The sessions were devoted to consideration of the following topics: the Americas a model for world cooperation, new world music, the rediscovery of America, military cooperation among the Americas, audiovisual aids to cultural understanding, health problems of the Americas post war relation of the Americas, American cultural relations and a cavalcade of America. One session on health problems of the Americas was addressed by Dr Morris Fishbein, Chicago, Editor of THE JOURNAL, chairman, Dr Ivo Jacques Dornelles, Brazilian member of the Pan American Sanitary Bureau and now a resident at the Memorial Hospital for the Treatment of Cancer and Allied Diseases, Colonel Albert R. Dreisbach, M. C., U. S. Army, Washington, D. C., medical division, Office of the Coordinator of Inter-American Affairs, Dr John R. Murdock, Panama, Pan American Sanitary Bureau and Dr Wilbur A. Staver, director, International Health Division, Rockefeller Foundation.

OHIO

The Rachford Lectures—Dr Hattie E. Alexander, New York, will deliver the eleventh annual series of the Benjamin Knowlton Rachford Lectureships in the Children's Hospital Clinic and Research Building, Cincinnati, November 12-13. Dr Alexander's subjects will be "Experimental Basis for Treatment of Hemophilus Influenzae Infections" and "Treatment of Hemophilus Influenzae Infections and of Pneumococcus and Meningococcus Meningitis."

Course on Military Neuropsychiatry—The department of psychiatry at the University of Cincinnati College of Medicine opened a fourteen week course on military neuropsychiatry October 23. Dr Charles E. Kelly, Cincinnati, gave the first lecture on "Neuropsychiatric Experiences in World War I." Others in the series are:

- Dr Philip E. Piker, Cincinnati, October 30, Induction, Neurologic Problems.
- Dr Charles D. Aring, Cincinnati, November 6, Induction, Neurologic Problems.
- Virginia T. Graham, Ph.D., Cincinnati, November 13, Induction, Psychologic Problems (Literacy and Mental Deficiency).
- Major Kenneth G. Moore, M. C., U. S. Army, Fort Worth, Texas, Military Laws and Regulations Concerning the Disposition of Psychiatric Patients.
- Dr Milton Rosenbaum, Cincinnati, November 27, Psychiatric Problems in Noncombat Military Activity.
- Dr Maurice Levine, Cincinnati, December 4, Psychiatric Problems in Combat Activity.
- Dr Joseph P. Evans, Cincinnati, December 18, Craniocerebral Injuries.
- Dr Eugene B. Ferris, Jr., Cincinnati, January 15, Certain Problems of Aviation Medicine.
- Dr Leon Goldman, Cincinnati, January 22, Certain Problems of Gas Warfare.
- Dr John Romano, Cincinnati, January 29, Some Effects of Modern Warfare on Civilian Population.

OKLAHOMA

Clinical Conference—The Oklahoma City Clinical Society will hold its twelfth annual fall conference at the Hotel Baltimore, October 26-29. The program will include general assemblies, postgraduate symposiums and round table discussions. The annual dinner Tuesday evening will be given by the local chamber of commerce. Dr James E. Paulin, Atlanta, Ga., President-Elect of the American Medical Association, will be the guest of honor. Guest speakers at the conference will include:

- Dr Isaac A. Bigger, Richmond, Va., surgery.
- Dr George M. Curtis, Columbus, Ohio, surgery.
- Dr Frank H. Everhardt, St. Louis, physical therapy.
- Dr Frederick H. Falls, Chicago, obstetrics.
- Dr Charles C. Higgins, Cleveland, urology.
- Dr Sara M. Jordan, Boston, internal medicine.
- Dr John Albert Key, St. Louis, orthopedics.
- Dr Byrl R. Kirklin, Rochester, Minn., radiology.
- Dr Andrew W. McAlester, Kansas City, ophthalmology.
- Dr Donovan J. McCune, New York, pediatrics.
- Dr Frank J. Novak, Jr., Chicago, otolaryngology.
- Dr Albert O. Singleton, Galveston, Texas, surgery.
- Dr Tom D. Spies, Cincinnati, Ohio, and Birmingham, Ala., internal medicine.
- Dr Howard C. Taylor, Jr., New York, gynecology.
- Dr Willard O. Thompson, Chicago, internal medicine.
- Dr Eugene F. Traub, New York, dermatology.

OREGON

State Medical Election—Dr Thompson Coberth, The Dalles, was named president-elect of the Oregon State Medical Society at its annual session in Portland, September 13, and Dr George E. Henton, Portland, was installed as president. Other officers include Drs Edward H. McLean, Oregon City, Raymond M. McKeown, Marshfield, and John R. Montague, Portland, vice presidents. Dr Thomas D. Robertson is secretary and Dr James E. Buckley, Portland, treasurer.

PENNSYLVANIA

Society News—Dr Michael M. Wolke, Philadelphia, addressed the Schuylkill County Medical Society at Reading, September 8, on plastic surgery.—Dr Albert E. Russell, New York, discussed "Problems of Civilian Medical Service in War Times" before the Cambria County Medical Society in Johnstown October 8.

Philadelphia

Alvarenga Prize Lecture—The third Alvarenga Prize Lecture was delivered before the College of Physicians of Philadelphia and the Philadelphia County Medical Society, October 14, by Edwin J. Cohn, Ph.D., professor of biologic chemistry and head of the department, Harvard Medical School, Boston. His subject was "The Plasma Proteins: Their Properties and Functions."

WASHINGTON

New Industrial Hygiene Unit—The Washington State Department of Health and the U. S. Public Health Service cooperated in the establishment of an industrial hygiene division October 1. The new division will be housed in the same office building as the state department of health.

State Medical Election—Dr Vernie W. Spickard, Seattle, was chosen president-elect of the Washington State Medical Association and Dr Albert P. Duryea, Everett, was inducted into the presidency. Other officers include Drs Herbert L. Coe, Seattle, vice president, and Albert J. Bowles, Seattle, secretary-treasurer. The society has canceled future sessions until further notice.

Appointments to State Board of Health—Dr Harold L. Lawrence, Seattle, passed assistant surgeon of the U. S. Public Health Service, has been appointed chief of the division of epidemiology and venereal disease control of the Washington State Department of Health, Seattle. Dr Cedric Northrop, a member of the state department of health since December 1941, has been appointed chief of the division of tuberculosis control. Dr Arthur E. Lewis, U. S. Public Health Service Reserve, has been assigned to Washington as assistant state medical officer for civilian defense.

GENERAL

American College of Surgeons Cancels Meeting—The annual Clinical Congress of the American College of Surgeons which was scheduled to be held in Cleveland November 17-20 was canceled by the board of regents of the college at a meeting in Chicago October 14.

Southern Psychiatric Meeting Postponed—The annual sessions of the Southern Psychiatric Association will be postponed for the duration of the national emergency. The roster of officers and members will be frozen and all dues suspended until the emergency has passed. In the meantime Dr Newdigate M. Owensby, Atlanta, Ga., secretary-treasurer of the association, requests that he be kept informed of any change in address of members and be advised of all matters pertaining to the welfare of the association. The 1942 meeting was to be held in Richmond, Va., November 6-7.

Aero Medical Association—Dr Harold R. Bohlmann, Baltimore, was chosen president-elect of the Aero Medical Association of the United States at its annual meeting in Indianapolis, September 3-5, and Major William R. Lovelace, II, Wright Field, Ohio, U. S. Army, was inducted into the presidency. Dr David S. Brachman, Detroit, was reelected secretary. Included on the scientific program at the recent meeting, were:

- Dr J. R. Delucchi, captain, Argentine Military Aviation Republic of Argentina, Effects of Obstructing Blood Vessels and of Muscular Effort on Total Ventilation: Its Importance in Aviation.
- Dr Walter M. Boothby, Rochester, Minn., Recent Research in the Mayo Aero Medical Unit.
- Lieut. Col. David B. Dill, Ph.D., Aero Medical Research Laboratory, Wright Field, Dayton, Ohio, Man's Ceiling as Determined by Low Pressure Chamber Tests.
- A. H. Bulbhan, D.D.S., Rochester, Minn., Visualization of the Alveoli of the Lung, by Metal Injection and Corrosion Method.
- Col. Eugen I. G. Reinartz, Randolph Field, Texas, Neuropsychiatric Aspects of Aviation Medicine.
- Major Emerson M. F. Weaver, Randolph Field, Importance of Vision in Flight.

Rehabilitation Council Formed—At a meeting of the American Physiotherapy Association in New York in August a permanent council was formed to serve as an "observation post" for member agencies and as a channel for communication with federal and state agencies and with each other. The objective is to aid in the rehabilitation of members of the armed forces and of civilians. Dr Philip D. Wilson, New York, was elected chairman and Col. John N. Smith, Jr., New

York, director of the Institute for the Crippled and Disabled, vice chairman. Membership in the council is available to national associations interested in rehabilitation on election by the executive committee which is composed of Harry H. Howett, National Society for Crippled Children, Holland Hudson New York, director of rehabilitation, National Tuberculosis Association, Evelyn C. McKay New York, American Foundation for the Blind, Major Julia C. Stinson, army nurse corps U. S. Army, New York, American Nurses Association and Dr. George H. Stevenson New York, American Psychiatric Association. The work of the council is to be financed by means of registration fees from member organizations.

Academy of Pediatrics—The American Academy of Pediatrics will meet in annual session at the Palmer House Chicago November 4-7 under the presidency of Dr. Edward C. Mitchell Memphis Tenn. There will be clinics at the Children's Memorial Bobs Roberts Memorial, Michael Reese and Presbyterian hospitals. There will be a symposium on virus diseases with Jacques J. Bronfenbrenner, D.P.H., St. Louis, as chairman and one on pediatric gynecology with Dr. Goodrich C. Schauffler Portland Ore. as chairman. Panel discussions will be held on growth and development and allergy and immunotherapy with Drs. Joseph A. Johnston Detroit, and Bret Ratner New York as chairmen respectively. Roundtable discussions will include the following topics: adolescence, dermatologic conditions in children, sinusitis and colds, the newborn mental health problems in children, bronchial asthma, chemotherapy, posture and flat feet, abdominal diseases (vary interpretation), nutrition and deficiency diseases, diseases of the central nervous system, the Kenny treatment of poliomyelitis, prophylaxis and treatment of communicable diseases, prescribing of drugs and tropical diseases. A special session will be addressed by Dr. Frank G. Boudreau, New York, Thursday evening on "Medicine in the Post War World" and Sister Kenny will conclude the meeting with a demonstration on her treatment of poliomyelitis.

Association of Military Surgeons—The annual meeting of the Association of Military Surgeons will be held at the Gunter Hotel, San Antonio Texas November 5-7, under the presidency of Col. James A. Mattison, Glendora, Calif. The tentative program lists the following speakers:

Major Gen. James C. Magee M. C. U. S. Army Washington D. C.
An Appraisal of the Medical Department at War
Capt. William L. Mann M. C. U. S. Navy Washington D. C.
Basic Principles Involved in the Plans and Arrangements of the Navy Medical Service
Dr. Knox E. Miller Fort San Houston Texas The Contribution of the Public Health Service Toward War Activities in the Territory of the Eighth Service Command
Dr. Charles M. Griffith Washington D. C. Medical and Hospital Service Experience with Disabled Veterans of World War II
Major Gen. Charles R. Reynolds M. C. U. S. Army Fort Harrisburg Pa. Medical and Epidemiological Follow Up of Selective Service Men Rejected for Military Service
Brig. Gen. Addison D. Davis M. C. U. S. Army Carlisle Barracks Pa. Work of the Medical Field Service School
Col. Leonard G. Rowntree Washington D. C. Selective Service System—Wartime Problems of Selective Service
Col. Frank S. Gillespie British Army Medical Service Medical and Surgical Experiences of the British Army in the Middle East
Dr. Neil D. Bue Marlin Texas The Work of the State Medical Association of Texas on Procurement and Assignment Service for Doctors, Dentists and Veterinarians
Brig. Gen. Robert H. Mills D. C. U. S. Army Dental Corps Increases Its Responsibility

Physical Status of NYA Youths—According to a report released recently by the U. S. Public Health Service and the National Youth Administration, nine tenths of the youths from ages 16 to 24 in low income families are in need of medical or dental care. Two thirds of these young people, however, are physically fit for any kind of work. These findings are based on about 150,000 complete physical examinations of out of school youths on work programs of the National Youth Administration. This group of young people is believed to be representative of about twelve million American youths from low income families. As compared with other groups of the same ages, the general health of NYA youths is much the same as that of all American youths, but NYA young people have received less corrective attention for remediable defects, such as decayed teeth, than have other groups. The physical exam-

inations were made by local physicians and dentists and included an evaluation of each youth's employability in terms of his health status. According to the recommendations of the examining physicians and dentists, about one hundred and eighty five health defects in each hundred youths require medical or dental attention. Untreated dental caries was recorded for 83 per cent of the individuals who were examined by a dentist. The average number of untreated defective teeth per hundred youths was 472, or about 5 defective teeth per person. Over one third of the youths had defective vision, but most of the visual defects were slight. More than one in ten were 15 per cent or more below the average weight for their age, sex and height, over 5 per cent weighed 25 per cent or more above the average. Negro youths were found to have a lower rate of total carious teeth. Youths in certain geographic regions, notably the Rocky Mountain and West South Central census regions, had significantly higher rates of dental caries. Prevalent rates of defective vision were higher for females than for males, and higher for white children than for Negroes. The 150,000 physical examinations included blood serologic examination, urinalysis, stethoscopic examination, dental examination, Snellen chart reading, ear, nose and throat examination and in some cases chest roentgenograms and fecal examinations.

Southern Medical Association—The annual meeting of the Southern Medical Association will be held at the Hotel John Marshall Richmond, Va. November 10-12, under the presidency of Dr. Marcus Pinson Neal, Columbia Mo. At the general session Tuesday evening Dr. Perrin H. Long, Baltimore, will be presented with the association's research medal in recognition of his outstanding contributions to the knowledge of bacteriology and chemotherapy. Dr. Neal will deliver his presidential address on "The Unknown Man in Medicine." Among the speakers on the program will be:

Dr. John Shelton Horsley Richmond Recent Advances in the Study of Cancer
Dr. Charles R. Robbins Richmond The Relation of the Conjoint Tendon to the Permanent Cure of Inguinal and Femoral Hernia
Dr. Lee E. Sutton Jr. Richmond Acute Respiratory Obstruction in Infants and Children
Lieut. Col. Henry M. Thomas Jr. M. C. U. S. Army Atlanta Ga. Peptic Ulcer in the Army
Dr. Robert I. McMillan Winston Salem N. C. Ventricular Tachycardia as a Therapeutic Problem in Coronary Thrombosis
Dr. Robert Wilson Jr. Charleston S. C. Acute Hemolytic Anemia in Fertilizer Workers A New Industrial Hazard
Dr. Haven Emerson New York Progress Against Bacillary Dysentery
Dr. William Henry Schell Jr. Bethesda Md. Foods and Their Importance to the War Effort
Lieut. Col. Baldwin H. E. W. Lucke M. C. U. S. Army Washington D. C. The Pathology of Epidemic Hepatitis
Dr. Frederick O. Coe Washington D. C. Traumatic Lesions of the Urinary Tract
Major Leon H. Warren M. C. U. S. Army Bethesda Md. Patch Tests: Their Practical Applications and Limitations
Dr. Francis M. Rackemann Boston The Natural History of Asthma
Dr. Ernest Ruppel Indianapolis Prostatic Cancer: An Evaluation of Treatment by Castration
Dr. Lawrence Chester McHenry Oklahoma City Some Observations on the Maxillary Sinuses
Dr. Clyde A. Clapp Baltimore Compensatory Divergent Strabismus: Its Etiology and Treatment
Dr. Russell F. Bonham Houston Texas The Changing Status of Anesthesia in Civilian Practice During the War

A feature of the meeting will be a symposium on gastroenterology in relation to the war. Included among the groups meeting during this period are the National Malaria Society, the American Society of Tropical Medicine, the American Academy of Tropical Medicine, the Southern Branch of the American Public Health Association and Region Two of the American Academy of Pediatrics. The Women's Auxiliary to the Southern Medical Association will be addressed by Dr. William W. Bauer, Director of the Bureau of Health Education of the American Medical Association, Chicago, on the "American Standard of Health." Another feature of the Southern Medical Association meeting will be the Officers' Wartime Luncheon on Wednesday, which will be addressed by Dr. James E. Paulin, Atlanta, Ga., President-Elect of the American Medical Association on "The Value of Medical Organizations in the War Effort."

CORRECTION

Scranton Mothers in War Industries—Dr. Hubley R. Owen, director of the Philadelphia Department of Health reports that the news item entitled "Scranton Mothers in War Industries" published in THE JOURNAL, September 19, page 215, was in error, and that no such program is under way in Scranton. The source of the news item in THE JOURNAL was the Washington Evening Star of September 1.

Good Health of the Nation Notwithstanding the War

As reported from time to time in previous letters, the health of the nation has not only remained good in spite of the war but in some ways even shown improvement. This heartening report is once again confirmed. At a press conference the chief medical officer to the Ministry of Health said that provisional figures supplied by the registrar general showed that the death rate for the June quarter would be the lowest for any June quarter except in 1927, 1930 and 1933 and that the infant mortality would be the lowest for any June quarter except that of 1940. The number of cases of typhoid in the period January to August 1939 was 701. In 1940 it rose to 1,452 and in 1941 to 2,539. But in the present year it fell to 531. Cases of cerebrospinal fever, which numbered 10,024 in 1940 and 8,645 in 1941, were reduced this year to 4,766. The campaign against diphtheria had been a conspicuous success. Already 3 million children under 14, out of a total of 8¼ millions, have been inoculated. The vigilance of the medical authorities in all parts of the country is exemplified by the prompt measures taken recently in Glasgow to stamp out an outbreak of smallpox. A virulent oriental type was brought to that city in a ship. There were 41 cases and 8 deaths. All the cases except 4 occurred in Glasgow. The cases were traced and infection was combated by vaccination. The risks were tremendous, but it looked as though the epidemic had petered out. It was just over three weeks since the case which occurred in London had been notified.

Treatment of Burns of the Eyes in Wartime

The treatment of burns assumes a special importance in wartime. The Emergency Medical Services in Scotland have issued a memorandum which was compiled by a committee of leading surgeons with Sir John Fraser as chairman. In regard to burns of the eyes, they state that in burns of the face the eyelids frequently afford complete protection, so that only the surfaces of the lids require treatment. Coagulation methods are not suitable for the eyelids or for application to the skin over the malar region, as contraction of the coagulum may cause the lids to be drawn away from the eyeball with production of "exposure keratitis" and perhaps loss of a previously uninjured eye. In many cases the burns are superficial and require only application of sterile petrolatum. But if they are deep, glycerin-sulfonamide paste is preferable. This should be spread on thickly on sterile lint or gauze in the form of a face mask.

When the eye is involved, the essential part of treatment is rapid and efficient first aid, which should be confined to instillation of liquid petrolatum drops. Burns of the eye may cause severe damage by injuring the cornea and producing adhesions between the eyeball and the lids. To prevent these the conjunctival sac should be irrigated with isotonic solution of sodium chloride without delay. If this is not available, tepid water should be used. A few drops of a local anesthetic such as 3 per cent cocaine hydrochloride should then be instilled and the upper lid everted. In burns due to lime particles are often found adherent to the under surface of the upper lid and must be removed. If the burn is due to acids or alkalis irrigation must be thorough and prolonged, at least 200 cc being used for each eye. Spasm of the lids and edema of the conjunctiva may render examination difficult. The use of lid retractors after instillation of a local anesthetic will then facilitate

inspection. If, in addition, a few drops of a 2 per cent solution of fluorescein are instilled and then washed out with saline solution, the full extent of the damage becomes apparent.

Further treatment consists in the use of 1 per cent atropine sulfate drops twice daily (in all but the mildest cases) and instillation of 4 drops of liquid petrolatum every four hours. When atropine is used after middle life the tension of the eye must be kept under observation. The eye should be covered with pad and bandage. If adhesions appear to be forming petrolatum should be packed into the conjunctival fornix with a glass rod with a smooth rounded tip.

When the burn is complicated by the presence of multiple foreign bodies, as in injuries by incendiary bombs, removal may be difficult. Such foreign bodies should be removed a few at a time, at intervals of a day or two, the eye being treated with atropine and liquid petrolatum or cod liver oil drops in the interval. Only nonirritant antiseptics, such as sulfacetamide 25 per cent or merthiolate 0.01 per cent, should be used, preferably in the form of an ointment. If a local anesthetic is required for the relief of pain, cocaine, percarne or metycaine may be used. Repeated instillations of cocaine are contraindicated on account of the deleterious effect on the corneal epithelium. Where a burn involves the eyelids or eyeball, an ophthalmic surgeon should be asked to see the case early.

Dried Vegetables for Troops at the Front

Scientists at the Low Temperature Research Station Cambridge, have worked out a technique for drying vegetables under which they retain not only their taste and color but their nutritive value. The great merit of dried vegetables is their easier transportability. They enable men in the front line in Egypt to enjoy British potatoes, carrots and cabbage just as palatable and nutritious as when eaten at home. Indeed, it is claimed that they are more nutritious, for the utmost care is taken that they retain their minerals. Potatoes are peeled by machine and have blemishes and "eyes" removed. After washing they are shredded by a machine to small chips. They are then blanched by two minutes in boiling water and sudden cooling. They are next dried in a tunnel heated by steam. They are packed in tins from which all air is expelled and are replaced by nitrogen. The great compression achieved by drying is shown by the fact that the same shipping space will carry eight times as much potato, twenty times as much carrot and twenty to thirty times as much cabbage as in the fresh. The new process differs from drying fruit in the sun in that the essential nutritive elements are retained, and reconstitution with boiling water and cooking produces vegetables which look and taste as good as the fresh.

A Surgeon Helps to Save a Hospital

High explosive and incendiary bombs fell on a hospital, setting it on fire. The house surgeon Dr Philip Baxter wearing a dressing gown over his pajamas climbed a fall pipe to the blazing roof. Then he used the girdle of his dressing gown as a rope to hoist up buckets of water which were tied on by helpers below. He got the blaze under control. In leaping from the roof to a lower one he injured an ankle but went to the operating theater to attend the victims of the raid. When there a message came that an elderly woman was trapped under wreckage in another part of the town and that medical help was urgently needed. He went and had to crawl down a tunnel in the debris to administer morphine. He waited until she was extricated and sent to the hospital. He then hobbled back but was in great pain. While on his way a policeman lent him his bicycle. Cycling was no less painful but was quicker. On arrival he returned to the operating theater and continued his work. Only after he had been on duty for several hours did his own injury receive attention. His work helped to save the building from destruction.

New German Phosphorus Bomb

The Ministry of Home Security has issued the following advice with regard to the new German phosphorus fire bomb. Remember that phosphorus cannot burn when wet but bursts into flame as soon as it is dry. If you are splashed with burning phosphorus, keep the affected part under water or covered with a wet pad until medical treatment is available. If you can bathe the burn with a solution of 2 tablespoons of washing soda dissolved in a pint of water. On no account should any oily or greasy dressings be put on a phosphorus burn before it is certain that no trace of phosphorus remains, because grease dissolves phosphorus and spreads it.

Killing People on the Roads

Speaking at a meeting of the Royal Society for the Prevention of Accidents, Mr. Neol Baker, parliamentary secretary to the Ministry of War Transport, said that on our roads we were doing the same kind of killing and maiming that had been done on the battlefield for countless centuries. It was not tolerable that in a civilized country we should go on with this. In ten years we had killed on the roads as many as were killed throughout the blitzes on this country. He hoped and believed that the law could be so improved and that we should find ways in which it would be easier for the police to receive evidence which they require for prosecutions.

The war, because of traffic changes and the blackout, has caused some increase of road accidents. However, the figures of the past month show an improvement. During June 437 persons were killed on the roads, compared with 618 in the same month last year, 2,688 were seriously injured, compared with 3,592, and 8,408 were slightly injured, compared with 11,593. In the blackout hours 31 were killed, compared with 41, 118 seriously injured, compared with 314, and 305 slightly injured, compared with 567. The improvement is due to increased precautions.

The killed included 99 pedestrians and 12 pedal cyclists under 15. There were 365 children seriously injured while walking and 134 while cycling, and 1,280 slightly injured while walking and 605 while cycling. Ninety-five pedestrians, 75 motor cyclists and 76 pedal cyclists, all over 15, were killed.

Surgeon's Heroism in the Sinking of an Aircraft Carrier

In the sinking of the aircraft carrier *Eagle* in the Mediterranean the heroism of a surgeon deserves mention. With the flight deck tilted at an extreme angle he found a man with both legs broken. Although the ship was likely to sink at any moment he administered morphine and then passed a bow line round his patient's shoulders. Hanging on precariously himself he lowered the man until he slid gently into the sea and was later picked up by a destroyer. The surgeon went into the sea just before the ship sank, still with a box of morphine tubes in his hand. He was picked up by a destroyer, but before he could change his wet clothing another ship drew alongside packed with survivors. Hearing that there were wounded on board, he climbed on and administered morphine to a man with a smashed upper arm and set the fracture.

"The Flying Nurse"

"The flying doctor" has been succeeded by "the flying nurse." A new force consisting of "flying nurses" is being built up by the Women's Auxiliary Air Force. Eventually a nurse will travel in every air ambulance. The crew of an air ambulance are pilot, observer and an orderly of the Women's Auxiliary Air Force. She sits on a wooden box at the head of the patient within reach of the oxygen apparatus. She carries a flask of water and another of warm milk and has a hypodermic syringe ready for the relief of pain. A medical officer meets the ambu-

lance plane on landing to examine the patient and check his medical history. It has been found that the patients derive greater confidence and comfort from having a woman to look after them.

An American Appreciation

Dr. Virgil P. W. Sydenstricker, professor of medicine in the University of Georgia School of Medicine, who is carrying out investigations on nutrition in this country, stated that he had been agreeably impressed by the general appearance of well being. "My outstanding impression," he said, "is of the amazing and efficient job done by the Ministries of Food and Health in handling the situation." Provided the people used the food available properly, he saw no reason or excuse for trouble developing. Health officers in the areas he had visited informed him that the nutritional standard was better than before the war. This was no doubt due to increased employment and to the leveling out of the people's diet by rationing. He commended the scheme for the provision of school meals and milk for children.

BUENOS AIRES

(From Our Regular Correspondent)

Sept. 26, 1942.

Studies on Effects of Altitude

A law was recently passed by the senate which provides for the creation of an Argentine committee to take charge of the technical direction of studies on the effects of altitude. The committee will be a branch of the Ministry of Internal Affairs. It will be of an honorary character and consist of doctors of medicine, chemistry, physics and the natural sciences. The fields covered by the committee will be (1) studies of biologic problems in relation to most adaptable human biotype, (2) working capacity, feeding, housing and climatology, hydrologic, geologic, zoologic, botanic and physicochemical factors in relation to life of normal men in various altitudes, (3) pathology of altitudes, studies of diseases which may improve by hypothermy and the establishment of sanatoriums and hospitals in proper altitudes for the cure of certain diseases, (4) creation of portable laboratories and establishment of experimental hypologic centers and (5) studies of the animals and plants of different regions, the constitution of the soil, and meteorologic phenomena. Two hundred thousand Argentine pesos (\$50,000) was given by the Ministry of Internal Affairs to cover the expense of the studies. The motion for the creation of the National Committee of Altitudes was given by a group of research workers with Dr. Mariano R. Castex as head of the group. Their research was done on people who lived in the plateaus and highlands of Bolivia.

Antihemorrhagic Effect of Human Milk in Hemophilia

Drs. Mariano R. Castex and Alfredo Pavlovsky recently read a paper before the Academia Nacional de Medicina of Buenos Aires in which they reviewed the results of their research on the antihemorrhagic effect of human milk as reported by Sole of Vienna in 1935. It was observed that the substance which accelerates coagulation of the blood is suspended within the minute fat droplets in human milk. The authors found that coagulation is greatly accelerated in vitro when the cream of human milk is added to the blood of hemophilic patients. Coagulation is moderately accelerated when uncreamed human milk is added to blood, and it is not accelerated at all when cow's milk is used. They found that human milk, and especially the cream of human milk, contains a great amount of thromboplastic substance. Powdered milk, prepared by precipitation of milk with acetone, proved to be highly coagulating for blood. They isolated a precipitated fraction from human milk which was acidified with 1 per cent acetic acid solution by using the technique that Patek and Stetson used for isolating the globulin fraction from human plasma. They found also that fresh human

milk, and especially the cream of fresh human milk, produces spontaneous coagulation of ovalated plasma. Preserved milk loses the strength of its coagulating power. However, it regains the thromboplastin like power if calcium is added to it. Coagulation of ovalated plasma does not spontaneously occur when human milk is prepared with sodium ovalate. It occurs, however, if calcium is added to ovalated milk. The results indicated that the coagulating substance in human milk is thromboplastin. When blood plasma is deprived of prothrombin (by barium sulfate precipitation) human milk and its cream, alone or with calcium, does not coagulate blood plasma. The speakers reported good results from the use of the substance obtained from cream of human milk in controlling a dental hemorrhage in a hemophilic patient.

The Social Welfare of Children

Dr Luis Siri, the subdirector of the Direccion Nacional de Maternidad e Infancia, recently reviewed the progressive increase in centers for the welfare of children. The increase was 0.17 per cent from 1870 to 1880, 2.5 per cent from 1910 to 1920, 2.74 per cent from 1920 to 1930 and 3.22 per cent in the last decade, in which 28,000,000 Argentine pesos (\$7,000,000) was dedicated to this cause.

Dr T. Reca de Acosta said that in Buenos Aires there are ninety-four centers for recreation, education and social care of children between 2 and 6 years. Sixty-five are supported either by the government or by private institutions. In twenty-nine private centers the parents pay for the care and education given to their children. In 1936 there were in Buenos Aires 138,210 children in the preschool age. The total capacity of the recreational centers for children in the city in 1940 was for a total of only 5,000 children. There are seventy-seven parks, in the proportion of one park for every 1,866 children if the figures of the 1936 census are considered. Research carried on in sixty-one educational and recreational centers during the year 1938 to 1939 revealed an average registration of 3,600 children in each center. In the majority of the centers breakfast, lunch and dinner were given to the children.

Tuberculosis in Peru

Dr Ricardo Martinez of Lima recently published the results of his observations in Peru. A positive index to tuberculosis was found in 68.45 per cent in conscripts, 65 per cent in school children of Callao province, 77.98 per cent among the applicants for entrance to Lima University and 95 per cent in the various groups of teachers and unions of workers. The percentage of positivity in conscripts had the following regional percentages: 74.64 per cent in conscripts from coastal areas, 58.43 per cent in those from the mountains and 75 per cent in those in the wooded regions. The figures of positivity to tuberculosis in Peru are higher than those in Argentina, Brazil, Paraguay and Uruguay and lower than those in Cuba and Venezuela. Dr Leopoldo Molinari recently reported the results of roentgen examinations carried on in school children. Tuberculosis in evolution increased from 4.1 per cent in 1939 to 5.3 per cent in 1941. Secondary and tertiary forms also increased in the years 1940 and 1941.

A new tax law was passed in Peru by which all articles, especially cosmetics, will be sold with an antituberculosis stamp. The government will use the money for the construction and care of antituberculosis centers.

Endocrinologic Work in Montevideo

The Institute of Endocrinology of Montevideo was established in 1937. Dr J. C. Mussio Fournier, professor of endocrinology of the Faculty of Medicine of Montevideo and minister of public health of Uruguay, is the director. The institute is a center for research on endocrinology, the prevention and therapy of endocrinologic diseases and for postgraduate teach-

ing. The largest number of patients are those with endocrinologic diseases. The institute also has wards for gynecologic, neurologic, cardiovascular and otorhinolaryngologic diseases, and visiting nurses who regularly visit the schools for children to collaborate with the physicians of the schools for the diagnosis and therapy of endocrine disorders. About 2,000 school children are now under the medical care in the institute. The treatment of the patients is directed in the institute and carried on at home under supervision of the visiting nurses.

Personals

Prof. Dr. Mamerto Acuña, professor of pediatrics and puericulture of the Faculty of Medicine of Buenos Aires and director of the Instituto de Pediatría, retired from the faculty, having reached the age limit—Dr. R. M. Taylor of the Rockefeller Foundation and the head of the virus department of the National Department of Hygiene recently lectured at the Academia Nacional de Medicina of Buenos Aires on influenza—Dr. Abelardo Saenz of Montevideo, Uruguay, recently returned from Paris, where for fifteen years he was head of the department of laboratory research on tuberculosis of the Pasteur Institute. He published several articles on tuberculous bacillema, exogenic reinfection and tuberculous allergy. Dr. Saenz won the Pasteur prize, a silver medal, in 1939, when the institute celebrated its fiftieth anniversary. The prize was given because of his scientific contributions and devotion to bacteriology in the institute. The minister of war of France gave Dr. Saenz the important commission of being in charge of the sanitary condition of the Franco-Spanish border. Dr. Saenz was awarded the Boggio prize and a medal by the Academy of Medicine of Paris and the Henriette Regnier prize by the Academy of Sciences—Dr. Gerardo Laguardia, dean and professor of the Faculty of Medicine, recently died in Asunción, Paraguay.

Marriages

ALFRED LEON HOLLOMAN, Assistant Surgeon, U. S. Public Health Service, to Miss Helen Fulmer at Savannah, Ga., May 30.

CHARLES W. GEIGER to Mrs. Viola Karnstrom, both of Kankakee, Ill., in Bowling Green, Mo., June 29.

FREDERICK COOPER REHFELDT, Jackson, Miss., to Miss Ethel Evans Bennett in Fort Worth, Texas, recently.

WARREN MATAS KIRK, Louisville, Miss., to Miss Dorothy Kinkelberger of Wheeling, W. Va., June 20.

JOSEPH ALLISON CANNON WADSWORTH to Miss Martha T. Buchanan, both of Durham, N. C., recently.

JOHN GILMER MEBANE, Boston, to Miss Harriet de Berniere Elmore in Rutherfordton, N. C., in June.

ERNEST RANDALL BARNETT, Terre Haute, Ind., to Miss Mildred Ewing of Olathe, Kan., May 21.

WILLIAM VILARDO, Garfield, N. J., to Miss Helen Frances Beers of Ticonderoga, N. Y., January 3.

GEORGE ROBERT DAWSON JR., Charleston, S. C., to Miss Ada Frances Gilchrist of Rock Hill in June.

ROBERT SYDNEY PRESSMAN, Philadelphia, to Miss Reba Anna Melvin at South Mills, N. C., June 2.

KYLE E. BLACK to Miss Helen Elizabeth Apps, both of New York, in Attleboro, Mass., in June.

EMMETT SMYER BRANNON to Miss Anna Margaret Bond, both of Atlanta, Ga., July 4.

JOHN D. LECKY, Calvert City, Ky., to Miss Sara Watts Nickols of Glasgow, July 6.

ROBERT MORRIS to Miss Eileen Myers, both of Johannesburg, South Africa, May 5.

BRANHAM B. BAUGHMAN to Miss Matilda T. Hoge, both of Frankfort, Ky., July 18.

HUBERT R. OWEN, Atlanta, Ga., to Miss Esther Jane Corley of Boaz, Ala., recently.

Deaths

Carey Culbertson ⊕ Winnetka, Ill., Northwestern University Medical School, Chicago, 1898, specialist certified by the American Board of Obstetrics and Gynecology, Inc., member of the American Gynecological Society and Chicago Pathological Society, a founder and member of the Central Association of Obstetricians and Gynecologists, fellow of the American College of Surgeons, for many years clinical professor of obstetrics and gynecology at the Rush Medical College, Chicago and in 1941 when the school was taken over by the University of Illinois College of Medicine became professor of obstetrics and gynecology emeritus served as a major in the medical corps of the U S Army during World War I, formerly member of the board of health of Chicago and medical inspector of the public schools chief of the staff of gynecology at the Cook County Hospital Chicago, from 1925 to 1937 and for many years attending gynecologist attending obstetrician and gynecologist to the Presbyterian Hospital, Chicago, from 1908 to 1938 formerly consulting obstetrician to the Northwestern American Hospital, Chicago, member of the Chicago Historical Society, Institute of American Genealogy and the Oriental Institute of the University of Chicago at one time abstract editor of *Surgery Gynecology and Obstetrics* editor of Gregorio Marañón's book "The Climacteric and author of 'Surgery of the Female Pelvis' aged 71 died, October 9 in the Veterans Administration Facility Downey, of pneumonia

Arthur Douglass Hirschfelder ⊕ Minneapolis, Johns Hopkins University School of Medicine, Baltimore, 1903 professor of pharmacology at the University of Minnesota Medical School and professor of pharmacology and therapeutics at the University of Minnesota Graduate School assistant in medicine at the Cooper Medical College, San Francisco 1904-1905, formerly voluntary assistant, instructor and associate in medicine at his alma mater, associate fellow of the American Medical Association chairman of the Section on Pharmacology and Therapeutics, 1917-1918 and member of the House of Delegates in 1919 member of the American Society for Clinical Investigation the Society of Experimental Biology and Medicine, the American Society of Pharmacology and Experimental Therapeutics the American Physiological Society, the American Society of Biological Chemists the American Chemical Society and the Minnesota Academy of Science, pharmacologist in the war department in 1918 author of 'Diseases of the Heart and Aorta' and co-author of 'An Investigation of the Louse Problem', aged 63, died, October 11, of coronary sclerosis

James Torrance Rugh ⊕ Philadelphia, Jefferson Medical College of Philadelphia 1892, for many years professor of orthopedic surgery at his alma mater and since 1938 emeritus professor member of the American Orthopaedic Association and the American Academy of Orthopaedic Surgeons during World War I was commissioned a captain in the reserve corps of the Army and served as orthopedic surgeon to the Jefferson Unit number 38 was supervising orthopedic surgeon in camps in North Carolina, South Carolina and Georgia and after being commissioned a major was assigned to duty in the division of orthopedic surgery Surgeon General's Office became a lieutenant colonel formerly on the staffs of the Jefferson Methodist and Philadelphia General hospitals, in 1934 the senior class of the Jefferson Medical College presented his portrait to the college received the degree of doctor of laws from Gettysburg College in 1930, aged 75, died, October 12 at his home in Bala Cynwyd, Pa

Curtis Clyde Eves ⊕ Philadelphia, Medico Chirurgical College of Philadelphia, 1905, specialist certified by the American Board of Otolaryngology, member of the American Academy of Ophthalmology and Otolaryngology the American Laryngological Association, the American Laryngological Rhinological and Otolological Society, the American Otolological Society, Inc., and the American Broncho Esophagological Association served during World War I a member of the board of managers of the George School, formerly on the staff of the Hospital of the Protestant Episcopal Church, on the consultant staff of the Philadelphia General Hospital, on the consultant staff and at one time head of the ear, nose and throat service at the Bryn Mawr (Pa.) Hospital and the Pennsylvania Hospital where he died September 22 aged 66

Joseph Pilmoor Gilbert ⊕ Nashville, Tenn., Vanderbilt University School of Medicine, Nashville, 1923, member of the American Psychiatric Association formerly secretary and vice president of the Nashville Academy of Medicine served overseas during World War I, consultant psychiatrist for the Madison Rural Sanitarium and Hospital, Madison College,

and the Central State Hospital, on the general staffs of the Protestant Hospital and St Thomas Hospital, on the nursing school faculties of the latter hospital and the Nashville General Hospital, aged 48, died, September 3, of heart disease

Jesse Philip Van Keuren ⊕ Chester, Pa., Hahnemann Medical College and Hospital of Philadelphia, 1905, formerly served as civil service commissioner, past president of the Delaware County board of prison inspectors, for many years chief of the surgical staff of the J Lewis Crozer Homeopathic Hospital, Chester, on the staffs of the Childrens Hospital and St Lukes Hospital, Philadelphia, aged 59 died, September 10, in the Hahnemann Hospital Philadelphia, of staphylococci septicemia, fracture of the left hip and multiple abscesses

Julius Fernan Wenn, Milwaukee Rush Medical College, Chicago, 1902 member of the State Medical Society of Wisconsin, American Psychiatric Association and the Central Neuropsychiatric Association, served as a captain during World War I, formerly medical director of St Marys Hill, at one time on the staff of the Kaukahee (Ill.) State Hospital, formerly state inspector of private sanatoriums in Illinois aged 64 died, September 4 in the Sacred Heart Sanitarium of hypertensive cardiovascular disease

Regina Flood Keyes Roberts, Cheroo, China, University of Buffalo School of Medicine, 1896, formerly clinical instructor in obstetrics at her alma mater, at one time on the staffs of the Buffalo General and Erie County hospitals, Buffalo, organized and was head of a base hospital in Salonika, Greece, during World War I, was decorated by the French, Serbian and Bulgarian governments, aged 72, died July 10, while aboard the S S Conte Verde of a ruptured gallbladder

John Thomas Floyd, Atlanta, Ga., Atlanta College of Physicians and Surgeons, 1905, member of the Medical Association of Georgia at one time assistant to the chair of obstetrics at the Atlanta School of Medicine, served on the local draft board and as a captain in the medical corps of the U S Army during World War I, on the staffs of the Georgia Baptist, Crawford W Long and Grady hospitals, aged 61, died, September 7 of coronary thrombosis

Lewis Booker ⊕ New Castle, Del University of Virginia Department of Medicine Charlottesville, 1910, past president of the New Castle County Medical Society, served during World War I medical examiner for the county Selective Service System, aged 55 member of the state board of trustees of the Delaware State Hospital, Farnhurst, on the staff of the Delaware Hospital Wilmington, where he died, September 27, of acute coronary thrombosis

James Dwight Matthews, Detroit, Detroit College of Medicine 1892 fellow of the American College of Surgeons, served during World War I, formerly lecturer in anatomy at his alma mater, on the surgical staffs of the Providence, Woman's and Detroit Eye, Ear, Nose and Throat hospitals and the Detroit Tuberculosis Sanitarium aged 74, died, September 2 in the Veterans Administration Facility, Dearborn, of periculous meningitis

Edward Geddis Minor ⊕ Detroit, Detroit College of Medicine, 1912, member of the Radiological Society of North America Inc and the American College of Radiology, specialist certified by the American Board of Radiology Inc, aged 54, director of the x ray department of the Highland Park (Mich.) General Hospital, where he died September 9, of hypertensive heart disease and myocardial infarction

Walter Louis Migely Naperville Ill., Northwestern University Medical School, Chicago, 1910, member of the Illinois State Medical Society president of the board of health of Naperville past president of the Du Page County Medical Society and the Du Page County Tuberculosis Association, aged 58, died September 13 in the Copley Hospital, Aurora, of cerebral hemorrhage and hypertension

Robert Joseph Haley Sr, Paragould, Ark., Memphis (Tenn.) Hospital Medical College, 1899, member of the Arkansas Medical Society, past president of the Greene County Medical Society, formerly bank president and president of the city board of health president of the Dickinson Memorial Sanitarium from 1927 to 1940, aged 74, died, September 14, of coronary thrombosis

Lewis C Wessels, Philadelphia Hahnemann Medical College and Hospital of Philadelphia, 1892, founder of the division of ophthalmology in the city department of public health in 1907 and in 1893 medical inspector in the division of communicable diseases, on the staffs of the Woman's Homeopathic and Hahnemann hospitals, aged 81, died, September 4, of coronary occlusion

William Henry Clewell, Coaldale, Pa., Medico Chirurgical College of Philadelphia, 1896, veteran of the Spanish-American War, formerly president of the board of health of Coaldale, medical examiner for the district schools and a member of the county Selective Service System, aged 72, died, September 10 in the Palmerton (Pa.) Hospital of carcinoma of the pancreas

Lattie Graves ♂ Scottsville, Ky., Vanderbilt University School of Medicine, Nashville, Tenn., 1915 served for many years on the city school board, member of the Southeastern Surgical Congress, president of the Allen County Medical Society, aged 61, medical superintendent of the Graves Infirmary, where he died, September 20, of coronary thrombosis

Charles Hope Jaeger, New York, Columbia University College of Physicians and Surgeons, New York, 1896, specialist certified by the American Board of Orthopaedic Surgery, Inc., member of the American Orthopaedic Association consulting orthopaedic surgeon on the staff of the Lenox Hill Hospital, aged 66, died, September 12, of cerebral hemorrhage

William F. Grady ♂ Montclair, N. J., Long Island College Hospital, Brooklyn, 1908, member of a medical examining board during World War I, attending physician at Mount St. Dominic's Academy and College, Caldwell, aged 59 on the staff of St. Mary's Hospital, Orange, where he died, September 28, following an operation for appendicitis

Morris L. Simon ♂ Passaic, N. J., Columbia University College of Physicians and Surgeons, New York, 1912, served as a first lieutenant in the medical corps of the U. S. Army during World War I, formerly health officer of East Paterson on the staff of the Beth Israel Hospital, aged 52, died, September 1, of perforated gastric ulcer

Charles Henry Rannels Jr., Evanston, Ill., State University of Iowa College of Medicine, Iowa City, 1936, member of the Illinois State Medical Society, was called to active duty as a first lieutenant in the medical reserve corps of the U. S. Army March 7, 1941 and retired May 30, 1942, aged 29, died, August 23, of bronchial asthma

Adam Blasius Wolf, Brooklyn, Eclectic Medical College of the City of New York, 1907, examiner for a local draft board during World War I, aged 77, died September 17 in the Bethany Deaconess Hospital of prepatellar bursitis, arteriosclerosis and acute dilatation of the heart

Charles Magnus Pearson, Tacoma, Wash., Rush Medical College, Chicago, 1904, member of the Washington State Medical Association, served in the medical corps of the U. S. Army during World War I, aged 69, died, September 11, of coronary thrombosis

Bernard Albert Becker, Silverlake, Wis., Marion-Sims College of Medicine, St. Louis, 1898, member of the State Medical Society of Wisconsin, aged 72, was killed, September 14 when the automobile in which he was driving was struck by a train

John William Moore, Dialville, Texas, Georgia College of Eclectic Medicine and Surgery, Atlanta, 1893, member of the State Medical Association of Texas, aged 71, died, September 14, of uremia and a fractured hip received in a fall

Amos De Russia Wood, Bluefield, W. Va., College of Physicians and Surgeons, Baltimore, 1893, member of the West Virginia State Medical Association, aged 73, died, September 14, at the Bluefield Sanitarium of carcinoma of the stomach

Thomas Francis Manning, Rock Island, Ill., College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1902, aged 67, died September 7, in the Mercy Hospital, Davenport, Iowa, of abdominal carcinoma

Charles Joseph Walsh, Gilbertville, Mass., College of Physicians and Surgeons, Baltimore, 1892, member of the Massachusetts Medical Society, aged 83, died, September 6 in the Mary Lane Hospital, Ware, of cardiorenal disease

Charles Henry Duncan, New York, New York Homeopathic Medical College and Hospital, New York, 1905, aged 76, died, September 27, in the New York Polyclinic Medical School and Hospital of a self-inflicted bullet wound

Louis Spitz ♂ Philadelphia, Jefferson Medical College of Philadelphia, 1902, an Affiliate Fellow of the American Medical Association, aged 68, died, September 7, in the Mount Sinai Hospital of coronary occlusion and arteriosclerosis

Orvis L. William Hall, Boise, Idaho, University of Vermont College of Medicine, Burlington, 1883, member of the Idaho State Medical Association, aged 80, died, September 9, in Nampa of cerebral hemorrhage

Joseph Melnick ♂ Brooklyn, Long Island College Hospital, Brooklyn, 1925, aged 41, clinical assistant in pediatrics on the staff of the Jewish Hospital where he died, September 9, of lymphosarcoma of the colon

Clarence Trimble Ricketts ♂ Manchester, Ky., Kentucky School of Medicine, Louisville, 1906, mayor of the city of Manchester, aged 67, died, August 19, of coronary thrombosis and pulmonary embolism

Aubrey Leighton Loop ♂ Crawfordsville, Ind., Medical College of Indiana, Indianapolis, 1899, served during World War I, at one time county coroner, aged 67, died, September 5, of heart disease

Joseph Hill Winfrey, Glenallen, Va., University College of Medicine, Richmond, 1899, member of the Medical Society of Virginia, aged 70, died, September 7, in Richmond of coronary thrombosis

Moses Nathan Avery, Los Angeles, University of Michigan Homeopathic Medical School, Ann Arbor, 1881, formerly bank president, aged 97, died, September 9, of coronary occlusion

Francis Henry Schlink, Cleveland Heights, Ohio, Miami Medical College, Cincinnati, 1880, aged 86, died, September 16 in the Polyclinic Hospital, Cleveland, of uremia and nephritis

Eugene Joseph Kenny, Brooklyn, Long Island College Hospital, Brooklyn, 1889, aged 73, died, September 6, in the Hospital of the Holy Family of arteriosclerotic heart disease

Andrew J. Dodds, Pittsburg, Kan., Medical College of Ohio, Cincinnati, 1885, member of the Kansas Medical Society, aged 84, died, September 18, of chronic valvular heart disease

Charles Heinz Bishop ♂ Wichita Falls, Texas, Johann Wolfgang Goethe-Universität Medizinische Fakultät, Frankfurt-am-Main, Prussia, Germany, 1935, aged 36, died, August 18

Leo Risen ♂ Portland, Ore., University of Oregon Medical School, Portland, 1901, formerly on the staff of the Emanuel Hospital, aged 70, died, September 8, of coronary thrombosis

Richard P. Haas, Williamstown, Pa., Jefferson Medical College of Philadelphia, 1881, aged 85, died, September 19, of cerebral hemorrhage and chronic myocarditis

William Harper, Jersey City, N. J., Long Island College Hospital, Brooklyn, 1909, also a clergyman, formerly a medical missionary, aged 57, died, August 5

Lawrence W. Dolan, Erie, Pa., Medico Chirurgical College of Philadelphia, 1911, aged 56, died, September 14, in St. Vincent's Hospital of heart disease

Leon Edgar Norfleet, Tarboro, N. C., College of Physicians and Surgeons, New York, 1888, aged 78, died, September 12, of cerebral hemorrhage

Cloyd L. Souder, Safety Harbor, Fla., Medical College of Ohio, Cincinnati, 1880, aged 89, died, August 30, of coronary occlusion and arteriosclerosis

Posey G. Hurst, Oceana, W. Va., Kentucky School of Medicine, Louisville, 1905, aged 63, died, September 14, of myocarditis and a fractured hip

Frederick A. Clapsadel, Hessel, Mich., Cleveland University of Medicine and Surgery, 1897, aged 75, died, August 23, of cerebral hemorrhage

Byron Noble Gantz, Fairfield, Iowa, Hahnemann Medical College and Hospital, Chicago, 1885, aged 81, died, August 16, of chronic myocarditis

Thomas Webster Edgar, New York, University and Bellevue Hospital Medical College, New York, 1913, aged 52, died, August 8

Alonzo Teegarden Holt, Los Angeles, Kansas City (Mo.) Medical College, 1875, aged 88, died, August 22, of chronic myocarditis

Henri Lacourciere, Beauport, Que., Canada, School of Medicine and Surgery of Montreal, 1883, aged 88, died, August 16

Howard Greene Barrie, Paris, Ont., Canada, Trinity Medical College, Toronto, 1899, aged 68, died, August 19

James B. Quinn, Quincy, Mass., Maryland Medical College, Baltimore, 1913, aged 51, died, August 7

DIED WHILE IN MILITARY SERVICE

Josiah Dozier Bancroft ♂ Birmingham, Ala., Tulane University of Louisiana School of Medicine, New Orleans, 1931, was commissioned a captain in the medical corps of the U. S. Army and on May 13, 1942 was assigned to active duty at Camp Rucker, where he died, September 1, of coronary embolism, aged 39

Bureau of Investigation

CEASE AND DESIST ORDERS

Abstracts of Certain Federal Trade Commission Releases

The work of the Federal Trade Commission, in helping to protect the public against misrepresentation or fraud in the medical as well as other fields, has been greatly extended by the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act. The Food, Drug and Cosmetic Act of 1938 added to the Food and Drug Administration's control of the advertising claims and statements made on the labels of medicine or on the carton or in the accompanying leaflet, whereas what might be termed collateral advertising, that which appears in circulars, newspapers and magazines and over the air, comes more actively under the purview of the Federal Trade Commission by virtue of the Wheeler-Lea Amendment.

THE JOURNAL has at various times commented on the activities of the Federal Trade Commission in this connection even before the Wheeler-Lea Amendment gave it its added rights. In some cases the Commission may accept from the person or concern involved a stipulation that the objectionable practices or claims cited will be discontinued. In other cases the Commission issues what is known as a Cease and Desist Order, in which the individual, manufacturer or distributor cited is ordered to cease and desist from practices which have been declared objectionable. In some cases the claims cited have been discontinued by the firms several months (or even longer) before the issuance of the order. Abstracts of some of the orders issued in 1942 follow.

Alcoban—The promoters of this must no longer represent that it constitutes a competent or safe treatment for alcoholism or issue any advertisements which fail to reveal that the use of the product may produce toxic conditions in the body and result in serious injury to the nerves heart and lungs. This prohibition the outgrowth of a complaint initiated in March 1939 was issued in March 1942 by the Federal Trade Commission in an order brought against Western Chemicals, Inc. Maffett Sales Corporation, Bartell Drug Company, Frank L. Wilson, N. B. Wilson and Reuel K. Mount all of Seattle. In THE JOURNAL Jan 10 1942 page 163 there appeared brief mention of a case in which the Commission in January 1941 had ordered an Edwin L. Leisenring trading as U. S. Drug & Sales Company, U. S. Drug Laboratories and U. S. Drug Company and Gordon Leisenring both of Denver to cease representing that a product they were selling as Alcoban was a safe and competent treatment for alcoholism and to discontinue any advertisements which failed to reveal that the use of their nostrum might result in serious injury to the nerves tissues and lungs and might produce toxic conditions in the body. No connection between the Denver and Seattle concerns however is evident although each sells an 'Alcoban'.

BonKora—In July 1941 the Federal Trade Commission issued a complaint against the advertising claims for this product promoted by Battle Creek Drugs Inc., Battle Creek, Mich. and Consolidated Royal Chemical Corporation, Chicago, trading as Consolidated Drug Trade Products and as BonKora Company. In February 1942 these concerns were ordered by the Commission to discontinue the following misrepresentations that BonKora is a popular cocktail preparation that if taken as directed it will relieve or overcome obesity or reduce excess fat without dieting that it will reduce fat from designated parts of the body and that it contains no dangerous drugs and may be taken repeatedly with safety. Also ordered discontinued were any advertisements which failed to reveal that the product should not be used by persons suffering from nausea vomiting abdominal pains or other symptoms of appendicitis provided however that the advertising might limit its warning to the statement: Caution use only as directed when the labeling of the product made clear the potential dangers in using the preparation. According to the order BonKora is a saline cathartic containing epsom salt supplemented by the laxative action of buckthorn and cascara bark and its continued use may be habit forming in causing the user to become dependent on a laxative for the evacuation of the bowels.

Charles of the Ritz Rejuvenescence Cream—In October 1939 the Federal Trade Commission issued a complaint against the Charles of the Ritz Distributors Corporation, New York, charging that the use of the word Rejuvenescence falsely represented that this product would rejuvenate the skin or restore youth or the appearance of youth to the skin of the user. In May 1942 the Commission ordered the concern to discontinue these misrepresentations.

Chumanie Products—As the follow up of a complaint issued in July 1941 by the Federal Trade Commission an order to cease and desist from misrepresenting the therapeutic properties of these nostrums was issued by the Commission in May 1942 against Charles Roehm trading as Chumanie Medicine Company, New Richmond, Ohio. Among other misrepresentations cited were that Chumanie's Iron Tonic Pills are an effective treatment for anemia except in those cases of anemia that result from a deficiency of iron in the diet or that the symptoms of feeling played out or of nervousness indicate a deficiency of iron in

the diet that Chumanie's Yellow Jacket Pills provide a stimulant to the kidneys except as a mild diuretic or an effective treatment for kidney or bladder disorders or for such symptoms as backache leg pains or swollen eyes that 'Chumanie's Double RR Tablets' constitute an effective treatment for rheumatism or inflamed painful joints or will have any therapeutic effect in the treatment of such conditions beyond mitigating the distress and discomforts thereof that 'Chumanie's Plantation C. M. Q. Capsules' are a treatment for the relief of the common cold and that Chumanie's Triple XXX Tablets constitute a safe or competent treatment for irregular or delayed menstruation. The promoters further were ordered to discontinue any advertisement which failed to reveal that use of this product may cause gastrointestinal disturbances pelvic congestion excessive uterine hemorrhages and in cases of pregnancy infection of the pelvic organs and blood poisoning.

Freeman's Pylotts—In October 1941 the Federal Trade Commission issued a complaint against Merritt Freeman Butler trading as Freeman's Products, Howard City, Mich. (formerly of Grand Rapids, Mich.) who promoted this product. In April 1942 the Commission ordered Butler to cease advertising that this product is a cure remedy or effective treatment for hemorrhoids will ease pain quickly or offer any value in promoting good health in excess of its laxative properties. The order also directed him to discontinue any advertisement which failed to reveal that this nostrum should not be used by persons suffering from nausea vomiting abdominal pains or other symptoms of appendicitis and that continued use might result in phosphorus poisoning and consequent deterioration of the bones. Butler was however, permitted to limit this warning in advertisements to the statement: Caution use only as directed provided that the labeling of the product would bear adequate warning of the potential danger in using the preparation.

Loughneys (Dr. A. M.) Dependable Guide to Self Help Anti Spasmodic Oyl and Bowelklean—In July 1941 the Federal Trade Commission issued a complaint against the promoters of these products who were Al. Moley Loughney and Roger G. Loughney trading as Dr. A. M. Loughney, Oakland, Calif. In April 1942 the Commission ordered these persons to discontinue advertisements which contained any of the following misrepresentations: that the Loughneys' program of treatment or their mechanical preparations whether used separately jointly or in combination with the program set out in their literature constitute a cure or remedy or safe treatment for asthma hay fever neuritis rheumatism bronchitis stomach and bowel disorders high blood pressure or diphtheria that Anti Spasmodic Oyl whether used alone or in any combination with Bowelklean and the recommended program is a cure or remedy or safe treatment for pharyngitis laryngitis chest or head colds or pneumonia or possesses sedative healing or disinfectant properties that Bowelklean whether used alone or with Anti Spasmodic Oyl and the program mentioned is a cure or remedy for constipation or intestinal putrescence other than the temporary evacuation of the bowels that it is of any value whatever in the treatment of catarrh acne mucus colitis or kindred ailments or is a safe treatment for nausea or upset stomach that the existence of such symptoms as sour breath coated tongue indigestion nausea lack of energy headaches or loss of appetite usually indicates that constipation or intestinal putrescence is the basic cause of such conditions. The Loughneys further were ordered to discontinue any advertisements of Anti Spasmodic Oyl which failed to reveal that its frequent use may cause oil pneumonia or those of Bowelklean which did not disclose that this nostrum should not be used by persons suffering from abdominal pains or other symptoms of appendicitis with the provision however, that if these warnings are carefully stated on the labels of the product the advertisements need contain only the statement: Caution use only as directed. The order further directed them to discontinue any advertisements of their program which failed to reveal that it should not be followed by persons suffering from undernourishment or diabetes.

Herolin Preparations—In December 1940 the Federal Trade Commission issued a complaint against the Herolin Company, Inc. of Atlanta, Ga. and its president Bert H. Rubin who promoted these products. In March 1942 Rubin and his concern were ordered by the Commission to discontinue making the following misrepresentations in their advertising: that Original Herolin Beauther Hair Dressing penetrates to the roots of the hair revives hair cells or makes hair grow or prevents dandruff or other scalp ailments and also to cease misrepresenting the alleged efficacy of their preparations Herolin Hair Gloss and Temple Oil Herolin Naxco Tablets and Herolin Female Tonic. The concern also was to cease implying that the therapeutic effects of Herolin Moonbeam Pills Herolin Moonbeam Tonic and 'Herolin Croup Salve' are in excess of certain temporary relief that they may afford and that Herolin Tetter Salve has any value in the treatment of dandruff beyond that of softening dandruff scales and facilitating their removal. The Commission further ordered the concern to cease advertising that Herolin Blood Tonic will build blood or offer any value in treating skin or blood disorders and that Herolin Healing Oil is capable of penetrating the skin to the muscles or joints or constitutes an effective treatment for rheumatism lumbago and other ailments and to discontinue advertisements which used the words 'Blood Tonic' as part of the name Herolin Blood Tonic and otherwise represented that it was such a tonic or used the word 'Healing' as part of the name Herolin Healing Oil. The company further was ordered to include in its advertisements the warning that the use of the Blood Tonic may result in chronic mercury poisoning and should not be used by persons having tuberculosis or goiter and to warn users of Herolin Healing Oil against repeated application because of possible consequences.

Magnesia S. Pellegrino—In October 1941 the Federal Trade Commission issued a complaint against the Codrin Corporation of New York which puts this out. In May 1942 the Commission ordered the Codrin concern to cease representing that this preparation will assure perfect digestion or health will not irritate the intestines is a distasteful and a competent treatment for constipation or stomach acidity.

or any disease, in excess of temporarily relieving constipation and reducing stomach acidity. The order further directed this concern to discontinue any advertisements which failed to reveal that the product should not be used in cases of abdominal pains, stomach ache, cramps, nausea, vomiting or other symptoms of appendicitis or that its frequent or continued use might result in dependence on laxatives. The concern however was permitted to limit this warning in advertisements to the statement "Caution: use only as directed" provided that the labeling of the product contained in appropriate warning of the potential danger in the use of the preparation.

McK Edwards Eczema Remedy—In September 1940 the Federal Trade Commission issued a complaint against a person known as McK Edwards of Valley, Wash. who put out this product. In February 1942 the Commission ordered Edwards to cease representing that his nostrum except in cases of fungus infection is a cure or remedy for or has any value in the treatment of eczema beyond giving relief in some cases from the symptom of itching that it is of value in treating ivy or oak poisoning or in these cases will do anything more than afford temporary relief. The order further prohibited Edwards from disseminating any advertisements which failed to reveal that the use of his preparation might in some cases produce an excoriating effect or an acute or painful rash on the skin or if employed on certain types of eczema might seriously aggravate the eczematous condition. It was permitted however, to limit this warning in advertisements to "Caution: use only as directed" when the labels of the product contained appropriate warnings. The Commission further reported that this product is a solution of salicylic acid, alcohol and water with a minute amount of ethyl acetate and pointed out that salicylic acid is frequently used in preparations intended for treating skin disorders but customarily in much smaller proportion than that present in the Edwards product.

M D Medicated Douche Powder—As the result of a complaint that the Federal Trade Commission issued in May 1940 that agency in April 1942 ordered Stanley Laboratories Inc. Portland Ore. and its president Edward A. Bachman to discontinue the following false advertising representations in the sale of this preparation that it is a dependable safeguard and an "effective reliable antiseptic powder" thus implying that it is a contraceptive or prophylactic, that it is a recent development of scientific research and is endorsed by physicians and surgeons that it will have any effect on bacteria in excess of its action as a mild antiseptic or offer any substantial value in the treatment of cuts, sores or burns. The order further prohibited the use of the letters "M D" in the name of this product, use of the picturing of a cross or any other simulation of the American Red Cross emblem alone or with the picture of a doctor or a nurse or employment of the word "Laboratories" in their corporate or trade name or in any manner representing that they own or operate a laboratory equipped for compounding medicinal preparations and for research in connection therewith.

Pink Ointment—In November 1941 the Federal Trade Commission issued a complaint against John B. Armstrong M.D. Topkahan trading as Pink Ointment Company who promoted this as a cure or remedy for eczema, poison ivy, ringworm, cuts, burns, bruises, athlete's foot and all kinds of skin irritations. In February 1942 the Commission ordered Armstrong to discontinue these misrepresentations and to limit the claims for its value to its antiseptic effect and to the results it afforded in giving temporary local relief due to its counterirritant, antipruritic and analgesic properties. The Commission learned that the product in question contained carbolic acid in sufficient quantities to be dangerous to the user's health. Accordingly the order further prohibited any advertisement which failed to reveal that the use of Pink Ointment may cause necrosis of the skin and tissues and systemic poisoning including irritation of the kidneys and that the danger of such injury will be increased if the skin surface to which it is applied is inflamed or broken. This order however permitted Armstrong to limit his warning to advertisements to the statement "Caution: use only as directed" when the labeling of the product contained appropriate warnings.

Queen Ann Hair Dye—In December 1941 the Federal Trade Commission issued a complaint against Clifford S. Donnell trading as Queen Ann Manufacturing Company Newark N. J. who put out this dye which also was known as Queen Ann Hair Coloring and "Queen Ann Liquid Hair Coloring". In February 1942 the Commission ordered Donnell to discontinue any advertisements which represented that this product was an amazing new hair dye which would preserve the natural beauty of the hair, make it smooth or silky, would stop it from growing gray or give gray hair a permanent coloring that it can be applied in half the time required to apply other hair dyes, is quicker drying or causes the hair to hold its color longer than all other dyes that it is used exclusively by better beauty shops or is endorsed by the State Beauty Commission of New Jersey. The order also provided for discontinuance of any advertisements which contained the word "manufacturer" as part of the trade name or which otherwise represented that Donnell owns or operates a manufacturing plant or makes this product himself. The Commission's findings were that the dye in question is not an amazing or a new one as advertised but is a coal tar preparation similar to many other hair dyes. Eight months earlier (June 1941) Donnell's concern was one of a number of dealers in hair dyes which had stipulated with the Federal Trade Commission that they would publish proper cautionary statements in connection with the sale of their dyes.

Ronni Mascara—In August 1941 the Federal Trade Commission issued a complaint against a New York firm known as Parfums Ronni Inc. which put out this cosmetic also called Ronni Cream Mascara and Mascara by Ronni. In March 1942 the Commission ordered this concern to discontinue any advertisement which represented that the product in question is smudge proof, waterproof, runproof or tearproof by use of any of the terms stated or other words or terms of similar meaning.

Sebrone and Waft—In August 1940 the Federal Trade Commission issued a complaint against the Sebrone Company Chicago formerly known as Seboron Laboratories Inc. In May 1942 the Commission ordered the Sebrone Company and its officers and directors as well as the Federal Cosmetic Sales Corporation Springfield Ill. which has sold the Sebrone product and one of its officers to cease representing that Sebrone is a cure or remedy for dandruff or has any value in treating that condition in excess of assisting in the temporary removal of dandruff scales and beneficially affecting superficial infections of the scalp sometimes associated with dandruff that the use of Sebrone will have any helpful effect on scars or remove scar tissue or possesses any value in treating conditions which cause baldness or that it will prevent baldness. The order further directed the promoters to cease representing through use of the terms "stops dandruff" and "ends dandruff" that Sebrone will permanently eliminate dandruff or that it constitutes a cure or remedy for the underlying conditions which may cause dandruff. Also the order prohibited the misrepresentations that the other product Waft will destroy or mitigate unpleasant body and foot odors except by temporarily masking them that it possesses value in treating any disease or condition causing excessive sweating will reduce excessive sweating to normal or have any effect on this condition other than the temporary one afforded by the use of an astringent. Finally the order prohibited the misrepresentation that Sebrone and Waft are new discoveries or recent developments of scientific research.

Sura—The Federal Trade Commission issued a complaint in November 1939 against one Fannie P. Fox, trading as Sure Laboratories Chicago who put out this product. In January 1942 the Commission ordered her to discontinue the following misrepresentations in her advertising that her preparation is a neutralizing agent, a breath purifier will destroy or arrest the causes of unpleasant breath or have any effect on that condition other than that of a perfume in temporarily masking such odors.

Vita Ray—In August 1940 the Federal Trade Commission issued a complaint against Sterling Products 170 Varick St. New York and the Vita Ray Corporation of Lowell Mass. Subsequently in May 1942 the Commission issued an order against these concerns reporting that its findings were to the effect that the promoters' cosmetic cream has no beneficial or therapeutic effect because of the addition of vitamins A and D that there is no scientific basis for the claim that there is any local direct or selective action at the site of application or that there is any local or systemic effect whatever. The respondents were also ordered to cease disseminating advertisements which represent that their cosmetic creams and oils have any added beneficial value on the skin by reason of their vitamin content.

Warner's Nostrums—These are put out by Warner's Renowned Remedies Company Minneapolis and include Warner's Renowned Prescription No. 6 Warner's Renowned Laxative Tablets and Warner's Renowned Alkaline Douche Tablets which are sold separately and in combination under the designation Prescription No. 6 Complete.

Prescription No. 6 Method and Formula No. 6 Method. As the follow-up of a complaint issued in May 1940 by the Federal Trade Commission that agency in March 1942 ordered the Warner concern to cease representing that its preparations either singly or in combination are cures, remedies or effective treatments for functional sterility have therapeutic value in treating any form of sterility or possess any properties which have value in promoting the functioning of the female reproductive organs.

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Cosmetics

The following items are abstracts of stipulations in which promoters of cosmetics have cooperated with the Federal Trade Commission to the extent of agreeing to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Priscilla Parker Breath Correcting Lipstick—This is put out by R. W. Appleton trading as Parker Bouldin Company St. Paul. In March 1942 he signed a stipulation with the Federal Trade Commission in which he agreed to cease representing that this product is effective in neutralizing offensive breath and that its ingredients are harmless. Further he agreed to discontinue any advertisements which failed to reveal that continued use of the lipstick over too prolonged periods of time might cause exfoliation of the skin provided however that such advertisements need contain only the statement "Caution: use only as directed" if the label contains an appropriate warning. According to the stipulation this lipstick contains a chemical resorcin. Appleton further agreed to cease using the terms "Breath Correcting" or "Deodorizing" in the brand name of this product.

Zenaida—That this will banish gray hair or restore the original color of the hair and will not stain the clothing, hands or scalp were misrepresentations which Eladio Santini and Sylvia Pietri trading as Dr. H. A. Pietri Company New York agreed to discontinue in a stipulation that they signed with the Federal Trade Commission in July 1941. They also agreed to drop the use of the prefix "Dr." in their trade name and to cease representing that Zenaida is made or offered for sale by a Doctor of Medicine.

Correspondence

"CONVULSIONS AND DEATH, PROBABLY FROM COCAINE"

To the Editor—I read with interest the query by M.D., U. S. Navy, "Convulsions and Death, Probably from Cocaine," in THE JOURNAL, September 12, page 166.

I think it might be a good idea for the inquirer to find out how the cocaine solution had been prepared and whether it was sterilized in an autoclave or if it had been exposed to high heat for considerable time, as a change takes place with the production of toxic substances, probably similar to hydrocyanic acid commonly called prussic acid, when high heat is used.

My attention was called to this matter years ago when I had two close calls. The first was a rugged patient aged 46, who did considerable public speaking and was bothered with hoarseness, caused by discharge from the posterior ethmoids. This patient had cocaine used in his nose for diagnostic purposes on various occasions and had shown no ill effect.

About this time I had another patient on whom a radical antrum operation had been performed, and cocaine had been used in her nose on numerous occasions.

The mixture that I was in the habit of using at that time was equal parts of 10 per cent cocaine and 1,000 epinephrine making the solution about 5 per cent cocaine. I had never experienced any ill effects from using the cocaine on either one of these patients. When I made up the cocaine solution myself, I was careful not to boil it with a direct flame or place it in an autoclave. I usually made the cocaine solution by adding hot water to the cocaine hydrochloride crystals and placing the bottle in a water bath for a short time.

I had a number of tonsillectomies to be done under local anesthesia at the hospital and brought my own cocaine to perform the operations. On leaving the hospital I replaced the cocaine which I had used with some of the cocaine used in the hospital, and it was this solution which I had used on both of these patients. I might say that the hospital had sterilized the cocaine solution by placing it in an autoclave.

In making topical application to both of these patients, all symptoms similar to those described in the query took place, namely, pallor, followed by slight cyanosis, and convulsive seizures of the hands and face, which condition gradually spread over the body with unconsciousness, also slow and jerky respiration.

I immediately put the patients on the floor, elevating their feet with the head well lowered, and began artificial respiration, to which both responded. I feel sure that the cocaine solution which had been sterilized in the autoclave at the hospital and which had been used on these patients was the cause of the trouble, and the method of preparing it with high heat in an autoclave decomposed the cocaine with the production of very poisonous substances and caused the symptoms.

In conclusion I would suggest that

- 1 Cocaine solution should always be made up fresh.
- 2 When used locally either topically or injected, it should be combined with epinephrine to prevent absorption.
- 3 The patient should be instructed to expectorate constantly and not swallow any going in the throat from the nose, as absorption takes place quickly from the stomach.
- 4 The solution should not be autoclaved.
- 5 Only cocaine from a reliable firm should be used.
- 6 The solution should be slightly acid.

E. A. STAPLETON, M.D., Albany, N. Y.

BRADYCARDIA (BELOW RATE OF 40) IN ATHLETES, ESPECIALLY IN LONG DISTANCE RUNNERS

To the Editor—A few months ago a letter was sent to me referring to an article in *Collier's* about mile running as a sport, in which it was stated that Cunningham has a normal pulse rate of 38, whereas Les MacMitchell has a normal pulse rate of 32. As a matter of fact, these heart rates are not as they were actually stated in the article published in *Collier's* for June 7, 1941 (pages 19 and 48) under the title "Kid Mercury" by Stanley Frank. In that article Dr. George Deaver of the Department of Physical Education at New York University is quoted as saying "The boy (Les MacMitchell) has the amazing heart beat of 38, one of the lowest on record."

Cunningham's heart beat was 40, and I understand Nurnus was 42. Those fellows will live a long, long time! This occurrence was questioned by the writer, and my first inclination was briefly to agree that a heart rate under 40 per minute does not normally exist, since I myself had not encountered or heard of such a bradycardia, although normal rates in the 40s and 50s are common. It seemed wise, however, first to inquire of others with considerable experience and, incidentally, to obtain first hand information from Cunningham and MacMitchell themselves. This research has been well worth while. Bradycardia caused by starvation does not have a place here, of course.

I have reviewed the electrocardiograms, and other evidence, of a small but clearcut group of four perfectly normal young men, all athletes, three of them long distance runners, and of one middle aged man with normal sinus rates graphically recorded at under 40 per minute. Actually the basal rates were measured at 38, 38, 37, 37 and 35, in order named these heart rates belonged to a Marathon winner, an aviator, a champion miler, a nonathletic middle aged man with slight hypertension and cardiac enlargement, and a champion two miler. Incidentally, Cunningham states that his heart rate has been noted as low as 45 at rest but not below 40, while MacMitchell, whose perfectly normal electrocardiogram, showing a rate of 37, he kindly sent me to examine, states that his heart beat at rest has dropped to as low as 31 per minute.

To Cunningham and to MacMitchell and to several physicians whom I have consulted, I would like to express my thanks. Also I would much appreciate hearing from others who have authentic information regarding heart rates under 40 per minute in normal persons. As an exception that proves the rule, these observations are important and should be useful both as general information and in particular cases, in furthering our knowledge of the range of the normal heart.

PAUL D. WHITE, M.D., Boston

VALSALVA'S METHOD OF INFLATING THE MIDDLE EAR

To the Editor—In the September 5 issue, page 4, in Carson's article on otolaryngologic problems, the question of Valsalva's method of inflating middle ear is discussed and the statement made that holding the nose shut and swallowing raises the pharyngeal pressure. This experiment does not inflate the middle ear but deflates it when the drum has been bulged out by expansion of the air in the tympanic cavity. The experiment was first described by Toynbee (cited by Politzer, Adam, A Textbook of the Diseases of the Ear). Valsalva's method is to hold the nostrils closed with the fingers and then blow the air outward. Both methods may be useful in aviation, one in flying upward the other in descending, but the two methods have directly contrary actions and should not be confused.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Dental Practice Act Revocation of License for Unlawful Advertising—The Missouri dental practice act authorizes the revocation of a dental license for unprofessional or dishonorable conduct, defined to include "(a) advertising, directly or indirectly, prices for professional services, (b) advertising, directly or indirectly, by means of large display, glaring light sign, or containing as a part thereof the representation of a tooth, teeth, bridge work or any portion of the human head, (c) employing or making use of, directly or indirectly, advertising solicitors or free publicity press agents." After a hearing, the dental board found the plaintiff, a licensed dentist, guilty of a violation of this section and revoked his license. The order of revocation was affirmed by the circuit court of St. Louis City, after a trial de novo, and the plaintiff appealed to the Supreme Court of Missouri.

The court could not agree with the plaintiff's contention that the law was so vague and indefinite as to violate the due process clause of the federal constitution. Reading the law as a whole, the court held that the term "professional services" was sufficiently defined for the purposes of the case by the section setting forth what constitutes the practice of dentistry. The term "indirectly," as used in the quoted provision means not directly, obliquely, in a roundabout manner, dishonestly. The word "advertising" obviously embraces something beyond mere public speaking before civic or social organizations. It signifies giving public notice especially by printed matter, such as circular letters, pamphlets, newspapers and magazines. The plaintiff contended that the words "advertising solicitors" mean solicitors of advertising and therefore do not make sense in their context. But the court pointed out that they may also mean solicitors who advertise, just as an advertising dentist would be a dentist who advertises. So also a "free publicity press agent" would be a press agent who obtains free publicity (not paid advertising) for the dentist. The expression "large display" signifies a display advertising exceeding most others of like kind in quantity or dimensions according to general opinion and common judgment. The plaintiff contended that the quoted provision was vague in that it was impossible to tell whether all of the acts mentioned must concur to constitute the conduct denounced or whether some one or more of them alone would offend. But, said the court, the provision runs in the disjunctive and the doing of any one of the several acts denounced constitutes unprofessional conduct.

The evidence, in the opinion of the court, was sufficient to support the order of revocation. The plaintiff operated two dental laboratories, the larger of the two having 5,000 square feet of floor space, one third of which was occupied by the laboratory and the remainder by dental offices. There was a line of demarcation between the offices and the laboratory but they were communicating. Patients entering the place would be received by a common receptionist for the two enterprise. The laboratory was incorporated under the name "Dr. Rust Dental Laboratories, Inc." It advertised widely, but Dr. Rust personally did not after the new dental practice act went into effect in 1937. The contention of the dental board was that the laboratory corporation and its advertising were carried on to attract business to Dr. Rust and his subordinate dentists professionally. He was the head of both activities. The laboratory did the work of taking x-ray pictures, making dental plates, repairing and refurbishing them. The dentists would examine the teeth and render various kinds of professional services, such as extracting, treating or filling teeth, taking molds of teeth and gums and fitting the plates. Among other things the plaintiff had an advertising company prepare and place on the front and rear of streetcars in St. Louis advertising placards 21 by 27 inches which publicized the corporation and portrayed a full upper set of teeth in a gum or plate. The addresses given were those occupied by the two dental offices. Dr. Rust's name

was in large print, the word "Dentists" in smaller letters, and below these in much smaller print appeared "Lab Inc." Unquestionably this advertising was intended to inure to the benefit of the professional side of the business.

The revocation of the plaintiff's license did not constitute cruel and unusual punishment. The court said that there were no extenuating circumstances so far as it could see. An offer of proof was made and excluded that the plaintiff was an advertising dentist in Chicago with nine offices until a regulatory law was passed in Illinois. Then he went to Wisconsin and practiced there as the Painless Parriner Company until a regulatory law excluded him. *Rust v State Board of Dental Examiners*, 216 Wis 127, 256 N W 919, abst J A M A 105 624 (Aug 24) 1935. The present proceeding was heard by the Missouri dental board in March 1938. The trial in the circuit court occurred in June 1939. Some time that year before the trial the plaintiff had a pamphlet printed and circulated in St Louis and vicinity at the head of which appeared his name, "Dr A J Rust Dentist," and his two office addresses. It was addressed 'To the People of Missouri' and was a diatribe on the prevailing high charges in dentistry. It challenged the "Missouri's Dental Organization." On the witness stand the plaintiff characterized the dental board as a kangaroo court, said there was more mechanical skill than medical skill in dentistry and expressed the view that dentists should be allowed to advertise. He was against the law. The plaintiff's professional history and all this recalcitrance were competent evidence on the question of whether revocation of his license was cruel and unusual punishment. In conclusion, the court held that the judgment of the trial court affirming the revocation of the plaintiff's license was proper.—*Rust v Missouri Dental Board* 130 S W (2d) 80 (Mo, 1941)

Veterinary Practice Acts. Revocation of License for "Gross Moral or Professional Misconduct"—On the ground that the petitioner, a licensed veterinarian, had maintained a professional connection with and lent his professional name to a person not licensed as a doctor of veterinary medicine, the state board of veterinary medical examiners after a hearing, revoked the petitioner's license to practice veterinary medicine. To review such order the petitioner appealed, by way of certiorari, to the Supreme Court of Minnesota.

The charges before the board were based on section 5851-8 of Mason Minn St, 1940 Supp, providing for the revocation of a license "when the holder is guilty of gross moral or professional misconduct." On all the evidence the court was of the opinion that there was adequate basis for the revocation order. It appeared that the petitioner, who resided at Willmar where he maintained his home office established a branch office" at Melrose with one Johnson, a lay person, in charge. To acquaint the public with this fact, a display advertisement—no mere professional card—was inserted in the local newspaper. It occupied one eighth of an ordinary newspaper page and was in large type. The advertisement stated that the petitioner, as "Veterinary Surgeon," was about to open in Melrose a "Veterinary office." On its face, it advertised "G A Johnson" in large type as "Supply Mgr." The sick mare involved in the instant case belonged to a farmer who was about to call another veterinary when, at the suggestion of a fellow townsman of Johnson, the business was switched to him. Being informed of the mare's condition, Johnson agreed to and promptly did arrive at the farmer's home. In the interim, however he had talked with the petitioner over long distance telephone and repeated what the farmer had told him. The ailment was diagnosed as spinal septicemia, and both oral and intramuscular treatment was prescribed. The petitioner instructed Johnson as to the treatment and agreed to come as soon as possible. Arriving at the farm, Johnson "looked at" the horse and administered the prescribed treatment. Later that evening the petitioner, and on subsequent occasions both the petitioner and Johnson, administered similar doses. The mare survived. The farmer paid for the "veterinarian service" (as indicated by his memoranda on the checks) the sum of \$15.50. The two checks were payable to "G A Johnson and E P Walker." Both were cashed by Johnson. There was substantial denial that Johnson kept any of the money but in the opinion of the court

the evidence was easily open to the inference that he did share in the payment. There was further testimony that over an area embracing at least three counties the petitioner maintained a network of "informers" in the persons of cream station operators, oil station attendants, restaurateurs and others likely to learn of occasion for veterinary service. Cards advertising the petitioner were placed in their establishments, and they were paid 25 cents for each telephone call made by them to the petitioner's "home office" informing him of a need for his service.

The petitioner contended that the statute, in its use of the general words "gross moral or professional misconduct" without limitation, explanation or definition, was void for uncertainty. To this the court could not agree. Complete certainty of definition is not required, especially when the attempt is to fix a standard of conduct rather than to condemn specific acts. In such case, the court continued, definition of the class of acts to which the statute applies must in the nature of things be general and comprehensive. The use of broad, flexible terms in fixing the standard is inescapable. Mere difficulty in ascertaining whether close cases fall within its operation does not nullify a statute if by the measure stated it can be determined with reasonable certainty whether particular conduct is disapproved. Continuing, the court said that it was not controlling but still notable that within any reasonable meaning of the statute, the activity of the petitioner was "professional misconduct." Procuring unauthorized practice or lending the professional name to another is a recognized professional misdeed.

On reargument, the court concluded that it had no power to modify the decision of the state board of veterinary medical examiners or to remand the matter for a rehearing. The board acted within its jurisdiction and the court could not say that it proceeded on other than a correct theory of law or that its action was arbitrary, fraudulent, oppressive or unreasonable. It was suggested, however, that the board had acted on the theory that its only power was to revoke the petitioner's license rather than to suspend it for a period. Whether that was so or not the court could not determine but stated that the power given to the board to revoke a license included the power to suspend. If the board acted on the assumption that it had no power to suspend, it proceeded on an erroneous theory and should grant a rehearing. The order of the board was affirmed, with the suggestion that if the board had acted under assumption that it had power only to revoke, it could reconsider the case.—*In re Walker's License, Walker v Coram* 300 N W 800 (Minn, 1941)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Isolated Myocarditis—The routine examination of 5626 hearts at necropsy disclosed 240 instances of myocarditis. This is exclusive of hearts of persons with contagious diseases and syphilis. Isolated myocarditis of the granulomatous variety was encountered in 1 and diffuse myocarditis in 14. Saphir presents clinical data on 13 patients. There were 12 instances of myocarditis and, although anatomically principally identical, neither clinically nor at necropsy were other lesions demonstrated which might be correlated with the myocarditis. The 1 patient with granulomatous lesions died suddenly without a history even suggesting disease. Nine of the 12 patients with diffuse myocarditis died suddenly. The death of 1 was attributed to coronary thrombosis. The twelve hearts were enlarged and dilated. There were no abnormalities in the pericardium or the endocardium. The myocardium was pale gray, often faintly tinged with yellow, with minute grayish streaks or larger areas of gray and white which varied but corresponded roughly to the relative age of the disease. Microscopically the lesions were diffuse and principally interstitial, although muscle fibers were also involved. Lymphocytes and endothelial leukocytes were the most commonly encountered cells, polymorphonuclear and eosinophilic leukocytes were also seen. Mast cells seemed more numerous than usual. Transitions from the inflammatory cellular exudate to scar tissue were encountered, but these accumulations never resembled those of rheumatic myocarditis. The heart with the granulomatous myocarditis was about normal in size. Throughout the myocardium there were irregular, yellowish white areas which tended to fuse. In places they reached the endocardium and formed minute nodules. The pericardium showed no change. Conspicuous were a number of giant cells, with nuclear distribution more or less toward the periphery.

The myocardium disclosed a diffuse infiltration predominantly of eosinophilic leukocytes and lymphocytes. Spirochetes or tubercle bacilli could not be demonstrated. Clinically the principal manifestations of isolated myocarditis, which is of unknown origin, in addition to the progressive myocardial failure, were a weak, rapid pulse, low arterial pressure and an increase in the area of cardiac dullness. Precordial pain may be present. The disease occurs at any age, although young people seem more frequently affected and therefore arteriosclerotic heart disease may be ruled out. Although nothing is known of the etiology, it seems imperative to examine other organs and structures for the causative agent, as in trichinosis or, perhaps, tularemia. A hypersensitivity, particularly to arsenic compounds, may possibly be responsible.

Acute Coronary Thrombosis in Industry—The reaction of the heart of 10 industrial workers, who applied for compensation benefits, to indirect injuries caused by exposure to toxic fumes, electricity, infections and foreign proteins is discussed by Lemoff. The patients believed that certain incidents in the course of their employment had caused acute heart disease. The most common diagnosis was acute coronary occlusion, although a better diagnostic term would have been acute toxic myocarditis or coronary circulatory insufficiency. The amount of damage was usually in direct proportion to the offending force. The physical status of an organ determines the response to such trauma. Every effort should be made to check the patient's story so that a fair clinical conclusion can be made. Oxygen want, as systemic infection and foreign protein, results in an excessive demand on the heart, which, if prolonged, is followed by structural and functional changes. Electrical shock produces dysfunction without organic changes. In gas poisoning blood tests should determine the qualitative and quantitative character of the toxin. The toxic action of gases depends on the concentration and length of exposure.

Auricular Fibrillation in Rheumatic Heart Disease—Kossmann and Connor report 3 unusual cases of rheumatic heart disease with auricular fibrillation. The patients had mitral stenosis of rheumatic origin with auricular fibrillation respectively for fourteen, sixteen and twenty one years. The abnormal rhythm began at an early age, and death occurred at 57, 33 and 45 years. This fact and other clinical data make it likely that rheumatic fever was the only etiologic factor involved in all. While under observation, aortic insufficiency developed in 1 and hypertension in another. Although congestive heart failure contributed to the death of each it was not the primary cause; the death of 1 was caused by gangrene of the ileum, and the sudden death of the other 2 suggested an embolic accident. One patient had four embolic accidents, two to the lungs and two to the lower extremities, exclusive of the final episode. The other 2 had no clinical evidence of embolization, except the terminal. Respectively for twelve, thirteen and fifteen years the 3 patients were gamfully employed despite the auricular fibrillation. Two of them were constantly under the influence of digitalis, while 1 took the drug irregularly.

Chronic Arthritis (Felty's Syndrome)—Lockie and his co-workers report 2 cases in which chronic arthritis, splenomegaly and neutrophilic leukopenia was associated with hepatomegaly, slight enlargement of the lymph nodes, normocytic anemia, monocytosis, loss of weight and slight fever. These cases are considered as representative examples of

so called Felty's syndrome in the broadest sense of the term. In the first case a chronic, nonspecific inflammatory reaction was the chief manifestation. The spleen and nodes showed sinus endothelial hyperplasia, phagocytosis, infiltration of plasma cells and eosinophils and thickening of cords. In the liver there were parenchymatous degeneration, edema, swelling of Kupffer cells and interstitial hepatitis. The pathologic and pathogenic basis of 'Felty's syndrome' is interpreted as arthritis in which not only the joints are affected but also other structures. Unless the essential features of the syndrome—splenomegaly, neutrophilic leukopenia and perhaps hepatomegaly—are thought of in relation with atrophic arthritis of adults they are liable to be detached pathogenically from the articular affliction and grouped separately under the guise of admittedly grave diseases, such as aplastic anemia, aleukemic leukemia, agranulocytosis, Hodgkin's disease, Banti's disease or as generalized specific infections such as tuberculosis and syphilis. These conditions must be excluded before a diagnosis is made. The first patient died two months after onset, apparently from neutropenia, splenomegaly and hepatomegaly. The second patient is alive four years after the signs of "Felty's syndrome" appeared. Splenectomy has been performed but what salutary results it has produced in the patient's well being and blood count are apparently only temporary. High voltage roentgen therapy provided some general symptomatic relief but no benefit to the enlarged spleen or to the neutropenia.

Estrogens for Gonorrheal Vulvovaginitis—Brown successfully treated 13 cases of gonococcal and 6 of nonspecific vaginitis with estrogens. Sulfanilamide or another sulfonamide derivative had been tried for varying lengths of time but in each case they failed to cure the vulvovaginitis. All the children treated with estrogen were cured bacteriologically and clinically. If the cases are properly managed (vaginal cornification maintained continuously for four weeks) failure will be infrequent. The estrogens were given parenterally. Only a few patients were treated with diethylstilbestrol and this was usually injected. The product and the dose used should be determined by the 'physiologic unit,' that is the amount necessary to cornify the vagina. The adoption of this unit has led to the use of much larger doses than are usually recommended. Complications which may be expected from this therapy are maturing of the genitals with the development of salpingitis and a permanent upset in the endocrine system of these young girls. The first complication did not occur, as the author has established a rule that estrogenic therapy shall not be used after a girl is 10 years of age or before if signs of early menarche (pigmentation and enlargement of the breasts, pubic and axillary hair or enlargement of the clitoris or labia) are present. In such patients there is cervicitis and not vaginitis and all will have varying degrees of vaginal cornification. If this rule is followed salpingitis should be extremely rare for three to four times the amount of estrogen is required to enlarge the uterus and open the tubes as it does to cornify the vagina.

Experience with adult patients and women in the menopause points to only temporary effects of estrogen. A subsequent disturbance in the patient's endocrine balance therefore need not be expected.

Boeck's Sarcoid with Nodular Iritis—Because of the rarity of ocular lesions in Boeck's sarcoid in children the Thornhills report such an occurrence in a Negro girl of 9. The differential diagnosis comprised tuberculous iritis, syphilitic iritis and Boeck's sarcoid. By physical examination, roentgenograms, intradermal tuberculin and Wassermann tests, repeated examinations of the sputum, inoculations of guinea pigs and microscopic study of a lymph node the diagnosis of Boeck's sarcoid was established. The course of the sarcoid is protracted with a decided tendency toward healing. The disease is rarely fatal. The patient was given a high caloric, high vitamin diet containing cod liver oil, ascorbic acid, thiamine hydrochloride and brewers yeast. One drop of 0.5 per cent atropine sulfate solution was used in the affected eye three times a day. During her stay in the hospital (four weeks) she had a temperature of 98.5 to 100.4 F but seemed to feel fine, ate well and gained 1½ pounds (680 Gm). The condition of the eye remained essentially the same; there was no improvement at discharge. One month later the vision in the affected eye (20/400) was unimproved. The corneal haze and descemetitis had cleared somewhat. Vascularization on the posterior surface of the cornea was seen. The pupil was poorly dilated owing to posterior synechias. Large cystic nodules on the iris had cleared. In the iris on the nasal side were four compact pinhead size yellow granules. Pigmented deposits were still present on the anterior surface of the lens. The posterior segment could not be visualized. Roentgen study of the chest showed considerable regression of the enlargement of the lymph nodes but the peripheral lung fields probably showed slightly more mottling than on previous examination. Roentgenograms of the hands, feet and long bones still revealed no cystic changes.

Precancerous Mouth Lesions of Avitaminosis B—Martin and Koop demonstrate from an analysis of the diets of 100 patients with precancerous stomatitis, 100 with oral cancer and 100 normal controls that degenerative and precancerous changes in the oral mucous membranes are among the important symptoms of deficiency disease and also that avitaminosis B is the greatest single cause of these precancerous lesions. The material was drawn from the Head and Neck Clinic at Memorial Hospital, where about 400 new cases of mouth and pharyngeal cancer are seen annually and from which at present about 1500 active cases of oral cancer are being followed. In most cases of intraoral cancer there are

in addition to the primary lesions definite degenerative (precancerous) changes in the oral mucous membranes which antedate the malignant growth. These degenerative and precancerous changes are due to some mild chronic irritation. It is probable that the most responsible irritant is the stomatitis of avitaminosis B, although several concomitant factors may be operative. At least three apparently unrelated types of clinical observations support the theoretical role of the B complex in the etiology and symptomatology of mouth cancer: the vitamin deficiency natures of (1) cancer cachexia, (2) radiation sickness and (3) precancerous stomatitis of obscure origin. Their analysis of the dietary histories of 300 subjects led the authors to begin treatment with the routine administration of vitamin B usually in the form of brewers' yeast, to all patients under treatment for intraoral cancer. The resultant beneficial effects were so gratifying that, although no methods for absolute statistical proof are as yet available, they nevertheless concluded empirically that the abnormal changes in the oral mucosa resulting from avitaminosis B are undoubtedly more prevalent and of more importance in the etiology of mouth cancer than any other single form of chronic irritation and possibly of greater significance than the sum total of all other etiologic factors. The abnormal changes of inadequate intake of the vitamin B complex vary widely, but generally the evidence is plain for at least a tentative diagnosis of avitaminosis B when an inflammatory lesion of the oral mucosa is associated with one or more of the following symptoms: malnutrition, mental depression, nervousness, insomnia, constipation, dermatosis and onychodystrophy. At the Memorial Hospital an investigation is in progress as to whether the incidence of an associated stomatitis (indicative of a B deficiency) is not more frequent in persons with esophageal, gastric and rectal cancer than in those not so afflicted.

Operating Room Deaths—In searching for some feature common to the twenty-three operating room deaths that occurred in ten years at the Royal Victoria Hospital it became apparent to Turner and Wilkinson that in all but a few of them asphyxia or oxygen deprivation of the tissues was a factor of the greatest importance. The progression of oxygen want or anoxia in these cases could be followed clinically, and at necropsy the effect of this anoxia was readily seen. Therefore it follows that those patients who exhibit a relative anoxia prior to operation are operative risks. This is because the anoxia already existent is almost certain to be heightened by the preoperative medication, anesthesia and through shock due to psychic or surgical trauma secondary to the operation itself. The following conditions had a bearing on the cause of death of the 23 patients: aortic stenosis, carotid sinus reflex, "pleural shock," shock, status thymicolymphaticus, air embolism, anesthesia and hemorrhage.

Endocrines in Anaphylaxis and Allergy—Farmer concludes, from a review of studies on the hormone influence in anaphylaxis, that endocrine glands have a distinct influence on anaphylactic reactivity. The influence manifests itself in enhanced or in diminished reactivity. The alteration is due to changes in antibody formation or in the sensitized animal's

capacity to react to renewed contact with the sensitizing antigen. The following observations are the bases for the foregoing assumptions: 1. Thyroidectomy prior to sensitization leads to a definite inhibition of precipitin formation (in rabbits) and to diminished severity of anaphylactic shock. 2. Thyroid in guinea pigs after completed sensitization enhances or diminishes the severity of anaphylactic shock, depending on the amount of thyroid administered. Thyroid in thyroidectomized sensitized rabbits and guinea pigs leads to normal or even excessive anaphylactic reactivity. 3. Hypophysectomy (in rats) prior to sensitization enhances the severity of the anaphylactic shock without exerting an influence on the production of precipitin. The influence of the endocrines on anaphylaxis has been established, but further experiments should be carried out stressing the quantitative considerations, sex and age of the animals. Ten cases of allergic conditions (hay fever and asthma) in women, evidently influenced by endocrinologic factors, are reported. Clinically they were related to the menstrual cycle, pregnancy and the menopause. Some were distinctly benefited by the administration of endocrine preparations and others by an ensuing pregnancy. The author does not attempt to explain the phenomena.

Rocky Mountain Spotted Fever—An average of 600 cases of tick fever are reported in the western endemic area yearly, and at least 200 appear each year in the remainder of the country. Baker believes that these figures are conservative, as many cases are not recognized by physicians unfamiliar with the disease. The average mortality is approximately 12.5 per cent. Tick fever has potentialities for great dissemination. Because of the many people who vacation each year in the Rocky Mountain area, the rapidity of present day transportation and the relatively long incubation period of the disease, infected persons may return home before any active manifestation is revealed and are cared for by physicians who have never seen a case of tick fever. Wider knowledge is essential, for the disease can in time assume proportions of national importance. The clinical picture is fairly typical, but confusion with other diseases is possible. Its prevention may be secured by simple precautions and by tick fever vaccine. At present its treatment is purely symptomatic and supportive. There is no recognized specific. Neosarsphenamine dissolved in an aqueous solution of metaphen is beneficial in rickettsial infections. Since tick fever has a striking clinical resemblance to endemic typhus, the two drugs were tried in 1934. Since then the author has had 3 to 4 cases of the disease under his care each season and all patients so treated have recovered. There has been less evidence of intoxication, minimal damage to the heart and kidneys and a more discrete, brighter colored nonhemorrhagic rash. Mental depression and nervous symptoms have been less severe. Convalescence was more rapid. The author is convinced that the drugs have a definite place in the therapy of tick fever.

Portal Thrombosis—Ten cases of aseptic thrombosis occurring in portal hypertension, verified at necropsy or at operation, are reported by Reich with a discussion of the etiology, symptomatology and therapy. The cases occurred at the Kings County Hospital from 1934 to 1940. The duration of the immediate illness varied from one day to one year, half of the patients complained for less than one week before admission. Nine of the patients were males. The spleen was enlarged in all but 3 and could be palpated in only 1 patient, who presented Banti's syndrome. The liver of all presented cirrhotic changes of varying degrees, was definitely palpable in 4, and its weight in 4 was definitely increased. The abdominal fluid was bloody on two occasions and purulent once. Ascites was not present in only 1 patient. Abdominal pain appeared in varying intensity and location in 8, toxemia in 6, jaundice in 6, gastrointestinal bleeding in 4, intestinal obstruction in 3, constipation in 3 and diarrhea in 2. Associated pathologic lesions were cholelithiasis, primary hepatic carcinoma, Banti's syndrome, adenocarcinoma of the tail of the pancreas, nonspecific granuloma of the gallbladder and heart disease. Terminal bronchopneumonia occurred in 4, associated venous thrombosis in 5 and pulmonary vessel occlusion (embolism and thrombosis) in 2. The cases seem to fall into four anatomic groups: portal vein thrombosis in portal hypertension due to portal cirrhosis, superior mesen-

teric vein thrombosis with intestinal symptoms predominating, involvement of the smaller radicles of the portal system (esophageal and gastric plexuses and splenic branches) and portal system thrombosis associated with carcinoma. The many factors of varying importance in the production of aseptic thrombosis of the portal system in portal hypertension are blood flow changes, changes in the veins, gastrointestinal changes favoring thrombosis, syphilitic vascular changes and tuberculosis, post-operative thrombocytosis, pressure of ascitic fluid, traction of adhesions, increased viscosity of blood, introduction of intravenous tissue extracts, chemical and toxic factors, schistosomiasis, splenic anemia, Banti's syndrome and primary disease of the portal vein. The chronic symptomatology of the underlying disease should not be confused with that of the superimposed thrombosis. In cirrhosis with ascites, gastrointestinal symptoms and splenomegaly portal thrombosis may be easily overlooked.

Peripheral Facial Paralysis in Hypertension—Merwarth reports 16 cases of paralysis of the peripheral portion of the facial nerve in hypertensive subjects resulting from hemorrhagic compression within the facial aqueduct. A likely source of hemorrhage is the petrosal artery. Interference with the blood supply from this vessel would also disrupt the circulation to the facial nerve trunk supplied by the vasa nervorum arising from the petrosal artery. Hemorrhage from or traction on the petrosal artery might possibly be the causative factor in producing the peripheral facial paralysis observed after operative approach to section of the posterior root. For hemorrhage to be a cause of facial paralysis the onset must be sudden, as it was in the 16 patients. This is true of hemorrhages in vascular rupture elsewhere in the nervous system. There was no preliminary pain or disturbance of taste. Some patients had previous attacks of hemiplegia or suffered from dizzy spells or headaches and were treated for existing vascular hypertension. The coexistence of high blood pressure with such an onset of paralysis should arouse suspicion of the possibility of aqueductal hemorrhage rather than inflammation as the cause of the paralysis.

Kaposi's Sarcoma—Aegerter and Peale report 4 cases of the disease commonly termed Kaposi's sarcoma. In 3 the process originated in the skin and in 1 death occurred as the result of hemorrhage from a visceral metastasis. In the fourth the tumor was limited to the heart. The authors believe that

the neoplasm in question is the cancerous representative of vascular tumors and that as such it should be called 'angiosarcoma' and the term 'Kaposi's sarcoma' should be reserved for the cutaneous subvariety.

Oral Ethinyl Estradiol for Menopause—Watson gave ethinyl estradiol orally to 18 women with menopausal symptoms. All patients were under treatment for two or more months and 1 for thirteen months. A toxic reaction, an urticarial rash, occurred in only 1 patient after taking only a small amount of the drug. This patient had had the same

reaction to diethylstilbestrol. Such a reaction might be a functional manifestation of a neurotic type. Relatively small doses of the ethinyl estradiol alleviated symptoms of the menopause and uniformly good results were obtained.

Methyl Testosterone Therapy in Hypogonadism—Pratt states that methyl testosterone orally initiated normal adolescent changes in a eunuchoid physician of 32. Toxic effects did not result from massive doses. There was a suggestion that tolerance to the substance may develop. Tolerance developed after six months when 100 mg daily was required to produce the response originally produced by 40 mg. Interruption of treatment for several weeks appeared to restore partial sensitivity to the hormone. The sole deleterious effect was a mild gynecomastia, which occurred only with larger doses.

Acute Mercury Poisoning—Wolpaw and Alpers administered sodium formaldehyde sulfoxylate to 20 patients with acute mercurial poisoning. All the patients had taken mercury bichloride in doses of from $7\frac{1}{2}$ to 45 grains (0.5 to 3 Gm). All vomited from five minutes to two hours after ingestion. The interval between its ingestion and therapy with sodium formaldehyde sulfoxylate ranged between fifteen minutes and thirty-six hours. Fourteen patients showed evidence of renal damage by changes in the urine. Colitis developed in 13. Mercury was found in the vomitus, washings or excreta in 16 of the 19 so examined. Of the 20 patients 16 recovered completely with no residual effects, 4 died. Anuria and uremia developed in 3 of these and 1 died in respiratory failure shortly after ingestion of the mercury, evidently from aspiration of vomited material or edema of the glottis. The doses of mercury bichloride of the 4 who died ranged from $22\frac{1}{2}$ to 45 grains. The interval between ingestion and treatment ranged from thirty minutes to three hours. The high incidence of colitis even early in the course of the poisoning makes prompt high colonic irrigations especially significant. The importance of early and intensive treatment both oral and intravenous cannot be overestimated. The fact that the substance formed by combination of mercury and sodium formaldehyde sulfoxylate is toxic should not be overlooked and supportive measures which encourage excretion by all routes must be maintained. Gastric lavage with the sulfoxylate is attended by certain dangers and requires careful individualized supervision, but until a more specific agent is discovered the drug deserves further trial.

Cirrhosis of Liver—The effects of an amino acid mixture were investigated by Fagin and Zinn in 5 random patients with a clinical diagnosis of cirrhosis of the liver. Four of them were in the decompensated stage of portal cirrhosis and 1 was in the compensated stage. In all jaundice had subsided before the study was begun. The mixture was administered intravenously to make certain that it actually reached the liver. It was administered daily after breakfast for four weeks in undiluted form over thirty-five minutes to four and a half hours. Reactions were few and mild. The first dose caused 3 patients to have an increased number of normal stools. The increase was attributed to hypermotility of the colon. This reaction did not recur after the first day. Slight nausea, occasional vomiting or a slight elevation of temperature with chilly sensations were occasionally observed only during the first week of amino acid therapy. One patient after the month of treatment was generally greatly improved, 3 were moderately improved and 1 remained unchanged. The most striking result was shrinkage in the size of the liver and spleen, possibly attributable to

resorption of intracellular fat in the liver, with circulatory readjustments secondary to the improved portal circulation resulting in a decrease in splenic congestion. Peripheral edema subsided within two weeks after treatment. Laboratory data indicated an improvement in dextrose tolerance and in hippuric acid synthesis in all patients, and an improvement in bromsulphalein excretion in 1.

Synthetic Vitamin E Therapy—Blakeslee used vitamin E therapy for 3 patients with peripheral neuritis associated with the Guillain-Barre syndrome, 1 with characteristic signs and symptoms of congenital amyotonia and 1 with the differential diagnosis between amyotrophic lateral sclerosis and muscular dystrophy of the Aran-Duchenne type. Each of the 5 patients showed definite improvement following the therapy. Further clinical trial of synthetic vitamin E in neuromuscular disorders is warranted by the encouraging effects observed in this and earlier studies.

Thiamine Clearance as Index of Nutritional Status—Four tests, the measurement of the basal twenty-four hour urinary excretion of thiamine, the fasting four-hour excretion, the response to the oral administration of 5 mg of thiamine and the four-hour excretion of the vitamin when 350 micrograms per square meter of body area was administered parenterally, were used by Melnick and Field to determine the vitamin B₁ status of 37 normal and deficient adult subjects. All normal subjects, but none of the deficient ones, excreted more than 50 micrograms of total thiamine during the four-hour period after parenteral injection. The omission of the major meal on the day when the parenteral test dose is given serves to counteract the minimal therapeutic value of the dose, so that the nutritional status of the subject during prolonged study is not significantly changed. Furthermore, the major portion of the parenteral test dose is excreted within the first four hours, so that no carryover effects are noticed.

Thiamine Requirement of Man—More than 175 normal and deficient subjects were used by Melnick to determine the thiamine requirement of man through urinary excretion studies. In the deficient subject dietary thiamine is conserved to replenish

depleted tissue stores and not wasted by urinary excretion. When a test dose of thiamine was superimposed on the dietary intake the extra vitamin was conserved or wasted (excreted), depending on the nutritional status of the subject. Objective thiamine balance studies indicate that the vitamin B₁ requirement of the adult is 350 micrograms per thousand calories. The recommended daily intake is 500 micrograms per thousand calories. Only 73 per cent of the so called normal subjects, who were not restricted as to choice of diet, excreted sufficient quantities of thiamine in the urine to pass all the thiamine clearance tests.

Boric-Butyn-Petrolatum Gauze Treatment of Burns—Hughes has had gratifying results in the treatment of burns of various degrees of severity with an easily available prepared dressing consisting of 40 strips of 3 by 15 inch gauze, 60 Gm of boric acid, 30 Gm of 2 per cent butyn and sufficient petrolatum to impregnate the gauze in the autoclave. The general principles of cleansing and debridement are carried out and then the boric-butyn petrolatum gauze is applied in strips of one layer thickness. A sterile dressing is superimposed. The burned area is redressed every two to three days after it is sponged with saturated boric acid. The only two disadvantages of the method are the difficulty in bandaging large areas and the necessity of redressing every two to three days, but its advantages are that the method is simple, the preparation is easily available, a clean wound, always under observation, is had, the patient is comfortable and the dressing is nonadherent. Comparison between silver nitrate-tannic acid and the boric-butyn-petrolatum gauze method showed that the side treated with the

gauze had healed by the ninth day, whereas the side having the eschar required several additional days. No infection or destruction of viable epithelium was apparent in any of the cases.

Rhinosporeidiosis in Texas—Pasternack and Alexander state that of the 12 cases of human rhinosporeidiosis reported in the United States 4 occurred in Texas, and 3 of these were seen in Houston, Texas being a livestock state, an animal reservoir may be present. The source of infection is unknown, but good epidemiologic evidence indicates that in certain localities the disease is probably water borne. All attempts to transmit the infection to lower animals and to grow the organism on various artificial mediums have failed. Attempts to germinate the spores have likewise been unsuccessful. The treatment of an early accessible single growth is to excise it and the surrounding area of healthy mucous membrane or skin. The treatment of an inaccessible growth is excision of the tumor and destruction of the surrounding area, preferably with the electric cautery.

Nonhemolytic Streptococci.—According to Colebrook and his colleagues nonhemolytic streptococci were predominant in swabs from 13 patients with local infection—7 of the patients had fever or suppuration—clinically resembling that due to the ordinary group A hemolytic streptococci. All the thirteen strains reacted with group A serum (precipitin test), eleven were agglutinated by type 12 serum and also absorbed agglutinin from it. The other two strains gave a type specific reaction with type 11 and type 25 serums. The eleven infections with type 12 strains followed a period in which hemolytic strains of type 12 had been spreading in the wards. Both the hemolytic and the nonhemolytic strains were insensitive to sulfanilamide. The mode of spread of these nonhemolytic strains remains obscure. They were derived from patients in five different wards, one of which was half a mile from the others.

Anemia in Women and Children on Wartime Diets.—Between September 1941 and January 1942 Mackay and her associates determined the hemoglobin concentration of 1074 persons living in London and the home counties, 364 children 6 months to 5 years, 128 school children 5 to 15 years, 38 factory girls 14 to 18 years and 544 nurses, medical students, factory hands and housewives more than 18 years of age. The results reveal a disquieting increase in anemia among the women and children. The mean hemoglobin of the nurses at a London teaching hospital was 90.6 per cent. That of the women students away from the hospital in London for two or more months was 84.1 per cent. These figures are both low in comparison with Price Jones's mean of 98.2 per cent for a strictly comparable group of nurses and women students in London and with Jenkins and Don's mean of 99.7 per cent for representative groups of supposedly healthy British women before the war. Of the London group 39 per cent and of the country group 83 per cent had values below the 90 per cent set by Price Jones. The women with the highest average hemoglobin level, 94 per cent were workers at a factory in a small town near London. They lived in their own homes and may have been able to supplement their rations with country produce. The East End housewives had an average hemoglobin level of 89.6 per cent. There was a high incidence of anemia among the children, the mean hemoglobin values being 75.4 per cent at 6 to 12 months, 72.8 per cent at 1 to 2 years and 81.8 per cent at 4 to 5 years. The highest mean hemoglobin values were those of children living in their own homes and attending welfare centers, the lowest were those of children in residential nurseries. The average hemoglobin level of county council school children 5 to 13 years of age was about 80 per cent and for those between 13 and 15 years of age it was 89 per cent. The adolescent factory girls had a higher hemoglobin level than any other group of any age studied. Their mean hemoglobin value was 98 per cent. The authors suggest that the present increase of anemia in women and children should be combated by educating the public concerning their special need to obtain a full share of iron-containing foods, including meat, by extending schemes for supplementing the diet of school children and pregnant and nursing mothers, and by the provision of an iron fortified milk and iron mixtures for babies and children. A dietetic

survey made it clear that hospital and other institutional diets, particularly those of emergency hospitals in the country, should be under constant review.

Convulsions Following Nupercaine Local Anesthesia.—In February 1941 generalized convulsions developed in a man after the injection of 1,000 nupercaine in isotonic solution of sodium chloride for a subcostal field block. The patient died on the operating table. In June and again in November Organe encountered instances with similar convulsions, fortunately without fatal result. The procedure had been used for some time without incident. In the first and third cases an overdose of nupercaine may have been responsible for the convulsions, although similarly large doses had been given on previous occasions in other cases without any untoward effect. The amount should be limited to 15 cc of the 1,000 solution per stone (64 kg) of body weight, and in its calculation allowance should be made for the presence of large tumors whose poor blood supply excludes them from sharing in its rapid absorption. In the second case the dose was correct, and was in fact less than that used on a later occasion, but severe jaundice and fever were present. In the presence of such complications it would probably be advisable to dilute the nupercaine to 1:2,000 and to use the calculated dose. This principle should probably be applied to all local anesthetic agents. The convulsions must be controlled early or else the patient will certainly die. Pentothal should be used even in the presence of circulatory collapse. Pentothal is preferable to pentobarbital or barbital, as their prolonged action is not necessary for the control of the convulsions and will add to the general depression. The dose must be minimal. Artificial respiration with oxygen is necessary and the circulatory depression will respond to saline solution intravenously. If necessary, epinephrine or ephedrine in minimal doses may be given to control the convulsion.

Influenza Virus B.—Burnet observed that antibody responses of human subjects to immunization with partially attenuated strains of influenza virus A were almost wholly limited to subjects with a low initial antibody titer. The experiments in volunteers have revealed a uniform immunologic response and offer presumptive evidence that an increased resistance to influenza virus B is induced in such subjects. The volunteers had a suitably prepared virus sprayed into the nose and the back of the throat. A blood sample was taken immediately and in three weeks, the two serum samples were compared for any change in antibody content. The virus used was derived from the mouse passage strain "Lee." No serious symptoms followed the spraying. Of those who on subsequent testing showed a rise in serum antibody level and therefore were presumably infected by the virus, 6 showed no symptoms, 2 noticed some increase in nasal secretion and stuffiness two days after inoculation, while 1 observed no nasal symptoms but had labial herpes five days after the inoculation. Normally, in him, herpetic attacks were induced by colds. A child of 10 given mixed virus, but reacting only to the B component, had a sharp onset of coryza with sneezing forty-eight hours after the administration. Serious nasal discharge and obstruction persisted for two days, but there were no toxic symptoms and no mucopurulent discharge. One subject showed a slight rise of antibody level by mouse test.

but none by Hirst's method and had a severe headache two days after inoculation but no fever or catarrhal symptoms. Therefore the strain appears capable of producing only trivial symptoms in only a few of those showing an active antibody response. The technique may provide a useful method of immunization against influenza virus B.

*Colloidal Gold Reaction of Blood Serum in Diagnosis of Diseases of Liver R Lavin A Sellek and A del Frade—p 203

Colloidal Gold Reaction of Blood Serum in Diagnosis of Diseases of Liver—Lavin and his collaborators resorted to the colloidal gold test for diagnosis of diseases of the liver in a group of 50 patients, adults and children with and without diseases of the liver and in a group of 20 normal children and adults for control. The test was carried out according to Gray's technique with some technical refinements in the preparation of the colloidal gold solution. The van den Bergh, bromsulphalein, galactose and Takata-Ara tests were also done on some patients (adults and children), whereas in adults the condition of the liver was verified by puncture biopsy, a surgical intervention or a necropsy. The test gave positive results in the blood serum of 7 out of 10 children with liver enlargement and strongly positive results in the blood serum of six children with syphilitic hepatitis, cirrhosis of the liver or catarrhal jaundice. It gave also positive results in the blood serum of 5 adults with cirrhosis of the liver, 2 adults with fatty degeneration of the liver, 2 with heart disease and liver stasis, 1 with jaundice and yellow degeneration of the liver, 2 with jaundice and 3 out of 5 with Parkinson's disease. The test gave negative results with the blood serum of children with nephrosis, polyserositis, tuberculous peritonitis and rheumatism and in that of 2 out of 5 adults with Parkinson's disease, in an adult with normal liver and an erroneous diagnosis of cirrhosis of the structure in 1 with jaundice and in patients with chronic heart disease as well as in those with primary tumor of the stomach with metastases in the liver and chronic gallbladder diseases. In the blood serum of 10 patients with syphilis and without any liver damage and in 19 out of 20 normal persons the test gave constantly negative results. The authors conclude that the colloidal gold test as practiced on the blood serum is one of the most sensitive liver function tests. They advise its routine use, together with other liver function tests, particularly the Takata-Ara reaction, which is specific for the diagnosis of cirrhosis.

Zeitschrift für klinische Medizin, Berlin

Sodium Chloride in Diet and Blood Volume—Krauel was interested not so much in the absolute values of the quantity of circulating blood as in the changes effected by increased and decreased sodium chloride intake. The determinations were always made on fasting persons who had had at least one hour of bed rest before the test was begun. First blood was withdrawn from the ear lobe for the determination of the hematocrit value. The quantity of plasma was ascertained by means of a dye method using a 1 per cent sterile solution of congo red. Studies were made on four groups of persons: (1) on normal persons who received a diet deficient in sodium chloride, (2) on patients with cardiovascular disorders who had received the same type of salt deficient diet, (3) on normal persons who had been subjected to daily sodium chloride tolerance tests of 20 Gm and (4) on patients with cardiac disorders who had received daily from 10 to 20 Gm of additional sodium chloride. In healthy persons the circulating quantity of blood decreased

after several days of salt free diet. In patients with cardiovascular disease the reduction in circulating blood is not pronounced under the influence of salt free diet if no cardiac remedies are given at the time. Salt free diet alone does not reduce the quantity of circulating blood of the majority of patients with heart disease. Daily oral administration of 20 Gm of sodium chloride effects in healthy subjects, in the course of several days, a noticeable increase in the quantity of blood, without the manifestation of subjective complaints. Patients with cardiovascular disorders react to the administration of sodium chloride regularly with a considerable increase in the quantity of blood, and this increase often has an adverse effect on the clinical picture.

Behavior of Vitamin C During Insulin Shock—Haid cites investigations which indicate that vitamin C plays an important part in the carbohydrate metabolism. He studied the vitamin C content of the blood in connection with the administration of large doses of insulin. The vitamin C content was determined before the injection of insulin, during the insulin shock and about six hours after the cessation of the shock. The vitamin C content of the blood decreased noticeably during the insulin shock. It is assumed that this is due to the fact that the vitamin wanders from the blood stream into the tissues, but particularly into the liver. There is evidence that it is the fact that vitamin C is a reducing agent which is responsible for its interference in the insulin shock. At any rate the decrease in the vitamin C content during insulin shock is a further proof of its close relationship to the carbohydrate metabolism.

Insulin Shock and White Blood Picture in Allergic Patients—Rausch and Bartelheimer demonstrate that the therapeutically employed insulin hypoglycemia produces in patients with asthma a change not only in the allergic manifestations but also in the white blood picture. Depending on the intensity of the increase in leukocytes produced by the insulin shock, two groups can be differentiated: asthmatic patients without inflammatory symptoms, in whom the total leukocyte count is at the most doubled, and those with accompanying inflammation in whom it increases to two three or four times the previous count. The neutrophil granulocytes are the ones which show the greatest increase during the augmentation in the total leukocyte count. The lymphocytes rise parallel with the neutrophil granulocytes until the maximum shock is reached, but thereafter the lymphocytes decrease rapidly. The eosinophils, after a preliminary increase, always decline below the initial value, toward the end of the insulin shock. The eosinophils remained uninfluenced in a patient with urticaria factitia. If epinephrine and histamine are injected at the height of the insulin shock there is a brief further increase in leukocytes.

Potassium as Tissue Diuretic—Bansi and Schwartz say that in earlier studies they found that potassium is capable of effecting the retroresorption of extravascular water. Potassium seems to promote the movement of fluids from the tissues to the circulatory system without influencing the hemodynamic factors of water metabolism. For this reason its use for patients with heart disease was limited, because adequate circulatory powers are required to carry the fluids that have entered the circulatory system to the kidneys. Potassium has its point of attack on the tissues, the water combining power of which is regulated chiefly by changes in the electric potential. In this report the authors describe attempts to activate the water elimination in obese persons by means of potassium. They used a potassium salt mixture with the high potassium content of 22.81 per cent. In 8 of 13 hydrophilic obese persons the potassium administration increased the diuresis and resulted in a loss of weight. However, this result is not always obtained. It is suggested that to obese persons with a tendency to water retention potassium be given in thrusts so as to counteract the swelling of the hydrophilic tissue. Potassium could be tried also in other disturbances of the peripheral water metabolism. Ascitic processes, except hepatic cirrhosis, might be suitable for the potassium therapy, also thrombosis of the leg with severe swelling of the tissues.

Book Notices

Treatment in General Practice By Harry Beckman M.D. Professor of Pharmacology Marquette University School of Medicine Milwaukee Wisconsin Fourth edition Cloth Price \$10 Pp 1013 Philadelphia & London W. B. Saunders Company 1942

The book by Beckman continues to grow in size and in circulation. This edition is prefaced by a statement in which Dr. Beckman points out that medical literature grows so rapidly that the task of evaluating new contributions and incorporating them into the text is becoming constantly more difficult. In the present edition many new diseases are included for the first time and there is also much new material. Such diseases as Q fever, schistosome dermatitis, target cell anemia and toxoplasmosis are examples of the necessity that every doctor assiduously endeavor to keep himself up to date. Special qualities of Beckman's book are its rationality and readability. Some of his aphorisms deserve quotation. After mentioning several treatments for glanders, he says "a grave disease, then, for which we have no remedy." The section on malaria is preceded by the famous poem of Ronald Ross. Under the treatment of chronic malaria he says "As I said earlier in this section there is need for a clear delineation of chronic malaria (What a fine task for some intelligent young man in the South to set himself to!)." In the section on the therapy of poliomyelitis he says "I have heard it said by an orthopedist who had watched Kenny at work in Minneapolis that in his opinion not everything that met the eye there was to be taken at quite face value. He was nevertheless quite convinced that the therapy of poliomyelitis would be advanced by Kenny's contributions." The section on diabetes is one of the most useful in this volume—well organized and exceedingly practical in its advice on diabetes. Here is a brief quotation from the introduction to the section on disturbances of menstruation:

There is nothing more fascinating to me in the whole of medical literature than the pretty pictures especially those in colors showing how the various anterior pituitary and ovarian hormones may be assumed to regulate the menstrual cycle. But there is no proof in that same literature nor even any strongly suggestive evidence based upon controlled clinical experimentation that such regulation can be effected at will by the administration of commercially available preparations of the allegedly specific hormones. I must still advise the reader as was done in the preceding edition of the book four years ago to spend his memorizing ability upon something other than the names of the sex hormone products of the competing pharmaceutical houses.

Especially valuable also is the chapter on dyspepsia, in which the author quotes extensively from the contribution by Alvarez. Exceedingly apt is the consideration of colitis and constipation under the title "Colon Consciousness."

The book runs the entire gamut of medical conditions, including everything from infection to infestation, all the forms of poisoning and other disturbances. At the end of the book there is a bibliography of some sixty pages indicating the vast literature that has been consulted as a basis. Altogether, Beckman is a most practical guide to current therapy.

The Dynamic State of Body Constituents By Rudolf Schoenheimer M.D. Harvard University Monographs in Medicine and Public Health [Number 3] The Edward A. Dunham Lectures for the Promotion of the Medical Sciences 1941. Cloth Price \$1.75 Pp 78 with 6 illustrations. Cambridge Harvard University Press London Oxford University Press 1942

The use of isotopes in the study of intermediary metabolism has given a picture of the state of living matter of contrast to the static theories formerly in vogue. The analogy of the combustion engine with its steady flow of fuel into a fixed system has been replaced by the concept that all constituents of living matter, structural or functional, single or complex, are in a steady state of rapid flux. Schoenheimer's pioneering efforts in the use of heavy hydrogen in labeling fatty acid molecules and his brilliant later work on amino acids and the formation of various excretory products are classics in this field. The three lectures in this short monograph were drafted by Dr. Schoenheimer and, after his untimely death, revised and delivered by Dr. Hans T. Clarke. They cannot be considered a review of the entire field of isotopic experimentation. Dr. Schoenheimer's theories are, however, well presented and the book deserves inspection by all those interested in keeping

abreast of the rapidly changing field of intermediary metabolism. The details of the methods of synthesis, isolation and analysis employed are not given, the entire discussion being confined to the results obtained and their physiologic application. A picture is given of the constant release and replacement of fragments of large molecules, of complex and interlocking biochemical reactions and the ceaseless interchange of essential radicals. Of particular interest are discussions of the part played by choline and methionine as sources of methyl groups, the participation of arginine in the urea cycle, the role of amino dicarboxylic acids in transamination, the formation of creatine from choline, arginine, aminoacetic acid and methionine via guanidoacetic acid, the nonparticipation of linoic acid in the interconversions of the other fatty acids, and the discovery that "essential" amino acids may be such because in some cases the amino group, in others the carbon chain, is indispensable. An extensive bibliography, with a series of general references, and a brief index are provided. As a tribute to Dr. Schoenheimer an appreciative biographic sketch by Dr. Clarke is incorporated as a foreword.

The Science of Health By Florence J. Meredith B.Sc. M.D. Professor of Hygiene Tufts College Medford Mass. Second edition of Twelve Hours of Hygiene. J. Cloth Price \$2.00 Pp 427 with 133 illustrations Philadelphia Widdicomb Company 1942

This is an excellent textbook on healthful living intended for use in college courses in hygiene to which one hour a week is devoted for one semester. The author uses many excellent diagrams, graphs and tables. Especially useful in a perplexed world should be the unusually good material in this book on personality adjustment and what would commonly be called mental hygiene. The portions which deal with such controversial subjects as alcohol, tobacco and narcotics are well and conservatively handled. The section on sex and reproduction is adequate. There is a good bibliography, a useful though not extensive list of organizations working for the health of the people (from which the author has intentionally excluded governmental agencies and, for some inexplicable reason, all professional organizations of doctors!), a table of official death rates for the latest year available (1939) and other tabular matter of general use, including two calory tables, one on a weight basis and one in hundred calory portions. The calory table in terms of pounds would have more usefulness in terms of more usual servings. This book, which replaces a previous edition under the title *Twelve Hours of Hygiene*, should continue the useful service of its predecessor.

Molecular Films: The Cyclotron & The New Biology Essays by Hugh Stott Taylor Ernest O. Lawrence and Irving Langmuir Cloth Price \$1.25 Pp 95 with 36 illustrations New Brunswick Rutgers University Press 1942

In this volume, three prominent scientists present concepts related to some of the unsolved problems in biology. The book is essentially a plea for greater cooperation among various sciences, particularly since new methods developed in one science may be especially applicable to problems in another. Thus, Dr. Ernest O. Lawrence describes the cyclotron, which has been of immense value in solving problems in biology and in medicine related to cytology in some diseases, the actions of enzymes, physiology and pharmacology. Dr. Irving Langmuir describes the use of the surface film technique for studying proteins, and the history of our approach to new problems with new methods is told by Dr. Hugh Stott Taylor. The Rutgers University Press has produced the book as a beautiful example of modern typography.

Synopsis of Ano Rectal Diseases By Louis J. Hirschman M.D. F.A.C.S. Professor of Proctology Wayne University Detroit Second edition. Fabricoid Price \$4.00 Pp 315 with 194 illustrations St. Louis C. V. Mosby Company 1942

The considerable experience of the author is reflected in this well established handbook of proctology. Written in a practical fashion, the little volume contains quantities of useful information. There are numerous illustrations, many of which are highly instructive and a number of which are in excellent color. The subject matter is confined to those diseases of the rectum and anus which are within the ken of the occasional rather than the constant practitioner of proctology. Anatomy, anesthesia and symptomatic significance and treat-

ment are first discussed. The author, it must be noted, has his own peculiar concepts of the anus and its diseases. Many of the methods of treatment are his own. There are, of course, a number of differences from standard methods described by others. It might be questioned whether the upper border of the anal canal should be placed at the dentate margin. For surgical purposes the author states that hemorrhoids can be considered as occurring in three distinct masses and he describes a technique suited only for this. The chapters on pruritus and constipation are a practical commentary on obstinate problems. It is obvious that in most instances the author is speaking with authority and wisdom. The student can gain much from a handbook of this nature but the general practitioner is likely to refer to it first whenever he desires information pertaining to the subject.

Encephalography By F. Crane Robertson M.D. M.R.C.I. F.R.C.I. Physician to Out Patients Royal Melbourne Hospital Melbourne. Monographs from the Walter and Eliza Hall Institute of Research in Pathology and Medicine Melbourne Number 2. Boards. Pp. 105 with 68 illustrations. Melbourne: C. G. E. Stewart & Company Limited New York: G. E. Stewart & Company 1941.

This is the second of a series of monographs financed by the Walter and Eliza Hall Institute of Research in Pathology and Medicine at Melbourne. The monograph is a lesson in the gross anatomy of the brain liberally illustrated by line drawings in color of the ventricular system by photographs of brain sections and, most importantly, by scores of clearly reproduced roentgenograms. For the most part these illustrate case reports. The procedure of encephalography is detailed and well illustrated. The author advocates the introduction of 30 cc. of air, a method saving of air and of patient discomfort but lavishly little attention. The monograph is principally useful as a demonstration of the detailed information which can be derived from the use of small amounts of air, and as an atlas of roentgenograms. Systematic analysis of results receives relatively little attention. The binding is fragile. The author is restrained in his evaluation of electroencephalography. "As experience increases, the number of cases subjected to this procedure diminishes." The monograph can be recommended to all who make use of the roentgen ray for study of the brain.

The Reception of William Beaumont's Discovery in Europe By Dr. George Rosen. With a foreword by Dr. John F. Fulton. Cloth. Price \$5. Pp. 97. New York: Schuman's 1942.

An interesting sidelight on William Beaumont's discoveries is this report of how the publication of "Experiments and Observations on the Gastric Juice and the Physiology of Digestion" by William Beaumont in 1834 was received in England, France, Germany and Italy. As is pointed out by Dr. John F. Fulton, on the basis of one well studied case Beaumont was able to change the course of medical thought in gastroenterology. The book is beautifully printed with special paper and bound in boards which reproduce pages of Beaumont's own manuscript. Any collection dealing with gastroenterology ought to possess this contribution to medical history.

Biological Symposia. A Series of Volumes Devoted to Current Symposia in the Field of Biology. Edited by Jacques Cattell. Volume VIII. Levels of Integration in Biological and Social Systems. Edited by Robert Redfield. Professor of Anthropology University of Chicago. Cloth. Price \$2.50. Pp. 240. Lancaster, Pennsylvania: Jacques Cattell Press 1942.

The papers in this book were read in a symposium held in connection with the celebration of the fiftieth anniversary of the University of Chicago. They include a series of studies covering the development and sequence of levels of integration, actually tracing the development of the body and the mind from the very lowest forms to the highest and in a way depicting the entire scheme of nature. Not only are individuals concerned but also societies as they exist among insect populations and mammals. The story is told from the coordination of single cells in establishing many celled organisms to the coordination of individuals into complex societies. In this connection the work of Dr. Robert E. Park shows that modern societies are far more free than primitive societies. In his concluding paper on 'Modern Society' Dr. Park points out that "the fact that men will still make war for a way of life indicates that the

development of integration is for human societies unfinished and implies that integration on a moral level is still of great importance and may become greater again."

The Electron Microscope By E. F. Burton. Head of the Department of Physics University of Toronto Toronto and W. H. Kohl. Development Engineer Rogers Radio Tubes Limited Toronto. Cloth. Price \$3.85. Pp. 233 with illustrations. 110 drawings by Dorothy Stone. New York: Reinhold Publishing Corporation 1942.

The interest of the physician in this book depends primarily on the usefulness of this device for the study of viruses, bacteriophage and tissues. Obviously the electron microscope is a tool of research and not of clinical practice. Those physicians who wish to keep abreast of scientific advances in general however, will find this a practical work. Especially enlightening are the introductory chapters on vision, light and similar basic subjects. The virus of influenza as determined by the use of the electron microscope is 12/1000000 centimeter. A red blood cell is 4/1000 centimeter. Obviously the electron microscope will find for us materials not previously determinable. The illustration showing the pneumococcus enlarged 67000 times reveals much that is important in relation to our studies of such organisms.

The National Nutrition By Morris Fishbein M.D. Editor of The Journal of the American Medical Association. Cloth. Price \$1.75. Pp. 192. Indianapolis & New York: Bobbs Merrill Company 1942.

In this volume the author has collected a number of essays on nutrition published from time to time in such periodicals as *Hygia*, *the Saturday Evening Post*, *the Red Book Magazine* and *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*. The material has been rewritten and brought up to date with special reference to the new campaign for improvement in national nutrition and to the special problems related to the war. The chapters include:

What Is National Nutrition?
Hollow Hunger and Hidden Hunger
Essential Food Materials
Commonsense and the Family Food
Review of Vitamins Facts and Follies
Commonsense and Your Weight
Meat Eating vs. Vegetarianism
The Hygiene of Food
Food and the War

The book is supplemented with tables covering essentials of a well balanced diet, food requirements that must be kept in mind in nutrition for the national defense.

Report of the Committee on Bed Bug Infestation 1935-1940 Medical Research Council Special Report Series No. 245. Paper. Price 1s. Pp. 64 with 9 illustrations. London: His Majesty's Stationery Office 1942.

Since a previous report on the bedbug was published by the Ministry of Health in 1934 much investigation and research have been instituted a report of which is presented in this pamphlet. The influence of temperature on the breeding, feeding habits and longevity of the pest is given in detail. Many insecticides and ovicides were investigated those recommended as most useful being heavy naphtha and hydrogen cyanide. Specific instructions for the use of each are given. A chapter is devoted to the construction of buildings so that they give a minimum harborage to bedbugs and in an appendix the problem of bedbugs in air raid shelters is discussed. There is an extensive bibliography.

First Official List of Motion Pictures on Food and Nutrition Compiled by Technical Committee on Evaluation of Motion Pictures. New York City Nutrition Program. Paper. Price 10 cents. Pp. 19. New York 1942.

The Motion Picture Committee of the New York City Nutrition Program with the assistance of the American Film Center, reviewed thirty-seven films on food and nutrition. The factors considered in the evaluation of the films were accuracy of subject matter, organization of material, quality of film presentation and educational value. Eleven films fulfilled all the conditions and are "recommended," while four other films, which did not meet all the standards but were still considered useful, are marked "accepted." These fifteen films are listed, with brief notes about the producer, distributor, rating, type of audience, the use, content and appraisal. The list is intended for distribution in New York City but is serviceable elsewhere.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

PATHWAYS FOR PAIN AROUND LARYNX FROM INFECTED TOOTH

To the Editor—A man aged 45 complained of pain over the region of the thyroid and cricoid cartilages on the left side and the midline. This pain could be intensified by pressure to these regions and was not located in the skin covering these areas. The superior laryngeal nerve was not tender and could be excluded. The patient had a thorough local and general examination which showed no pathologic condition. Two weeks afterward he noticed a swelling in the region of the left lower teeth which revealed an infected molar. After extraction of the tooth the pain in the laryngeal area disappeared completely. I explained the pain as being on the basis of a Head's zone. This author has described such laryngeal zones from lower molar disease. The lower teeth are supplied by the fifth nerve and it seems reasonable to establish a neuralgic connection between the fifth nerve and the area of the laryngeal cartilages probably on the basis of a so called false interpretation of pain by the pain centers in the brain. I should like to know which nerve area of the larynx was irritated in this case—in other words since the cartilages were tender to touch, what is the sensory innervation of the thyroid and cricoid cartilages or their perichondrium and what would be the approximate neurologic pathway of pain in this case? I found nothing in the standard anatomic textbooks concerning this question.

M D New York

ANSWER—The sensory impulses from the larynx are carried to the brain by way of the superior and inferior laryngeal nerves and probably also by sympathetic fibers. The superior laryngeal nerve innervates the larynx down to the lower rim of the vocal folds, the lower portion of the larynx. The tracheal mucosa is innervated for the most part by branches of the inferior laryngeal nerve. There are no known sensory anatomic connections between the vagus or its two ganglia and the trigeminal nerve, although in the medulla oblongata the fibers leaving the sensory and motor nuclei of the vagus surround and pass close to the substantia gelatinosa and the spinal trigeminal tract. All the lower teeth and part of the mandibula are innervated by branches of the mandibular division of the fifth cranial nerve. The skin, however, over the angle of the jaw and the inferior lateral surface of the mandibula is innervated by sensory branches of the great auricular nerve, as are parts of the outer ear, while the external acoustic meatus is supplied by branches of the vagus. Thus it could be possible that in case of a lower molar abscess branches of the great auricular nerve would be irritated and transmit impulses by way of the second cervical nerve, which also supplies the anterior and lateral region of the neck with sensory fibers (cutaneous cervical nerve).

Furthermore, it seems more logical that in this case the local abscess produced a lymphangitis and a possible lymphadenitis and stasis in the lymph circulation. The superior deep cervical nodes drain the face as well as the deeper structures of the head and neck and laterally lie close to the thyroid cartilage. Any disturbance or inflammation of the lymphatic pathways causes local pressure, which may be the cause of localized pain and may subside as soon as the focal source of infection is removed.

NOCTURNAL ERECTIONS IN MAN OF 57

To the Editor—A man aged 57 had a bilateral vasectomy four years ago following severe prostatitis and seminal vesiculitis. He has no retention or pus cells in the urine at this time but has frequent nocturnal erections. Could this be due to an increase of testicular hormones, especially androgens following vasectomy?

M D Missouri

ANSWER—The symptoms the patient complains of may be due to various causes, and often the etiologic factors are uncertain. Chronic prostatitis and seminal vesiculitis apparently are contributing factors in many cases. The usual treatment, consisting of vigorous prostatic massage, deep instillations of silver preparations and occasional dilations, will frequently give relief. Circulatory disturbances involving the penile circulation may be present in some cases. The cerebral centers of control are evidently involved in other cases. Oversecretion of androgens is not a probable factor, nor should it result from vasectomy. However, cases have been reported which have been controlled by giving the patient diethylstilbestrol. This substance can be administered orally in capsules, with a dosage of 2 or 3 mg daily for the first week, after which the dose should be reduced.

RANGE OF GASTRIC ACIDITY

To the Editor—If one uses a tube to drain the contents of a stomach and then gives a hypodermic injection of histamine what are considered the normal acids at fifteen minute intervals? I have been using the regular old Ewald test meal.

Clifton F West MD, Kingston N C

ANSWER—Various studies of the histamine stimulated gastric secretion in man have indicated a wide range in gastric acidity. Bloomfield and Pollard obtained volumes of from 15 to 60 cc. in a ten minute period, the highest total acidity ranged from 60 to 150 clinical units in 90 per cent of a series of normal patients. Ruffin and Dick observed a variation in the level of maximum free hydrochloric acid of from 30 to 85 clinical units in a large group of normal persons.

Palmer has noted similarly that the ten minute volume varies but at the height of secretion usually approximates 30 cc., and at this time the peak of the free acid curve usually ranges from 100 to 140 clinical units. It is most important to note that all ranges of acid secretion from 0 to 140 or 160 are encountered in normal persons with normal stomach as well as in the presence of disease. Consequently the old terms 'normal acidity,' 'hyperacidity' and 'hypoacidity' have no clinical significance.

It should be pointed out also that errors occur in the performance of the histamine test and that care must be taken to make certain that the tube is not in the esophagus or duodenum. There are rare cases of transitory achlorhydria, no free acid being obtained on certain occasions even though the tube is in the stomach and despite the fact that abundant free acid is found at other times.

Histamine proved achlorhydria is invariably and consistently present in pernicious anemia and subacute combined degeneration of the spinal cord and absent in chronic benign peptic ulcer. In all other conditions, including carcinoma the secretory range is wide.

POSSIBLE PURPURA

To the Editor—A retired farmer aged 57 weighing 137 pounds (62 Kg) and 5 feet 5½ inches (165 cm) tall is quite well nourished and appears to be in good health. His chief complaint is of attacks of red blotching discoloration of the skin which began about four years ago and was then confined to the lower portion of the legs and now involves the entire legs and to above the middle third of thigh. The appearance of red blotches is accompanied by intense itching which does not yield to any of the ordinary analgesics. On examination the skin is almost completely involved in both lower extremities up to the middle third of the thigh and small blotches are present up to the hips. The involved portions are relatively smooth but are slightly elevated above small patches of uninvolved skin. The areas are bright red where the condition is receding there is a brownish discoloration as from a bruise. It seems that there is an extravasation of blood into the skin and not under the skin and the slight stretch due to this fluid in the skin seems to cause the itching sensation. Anything that may be suggested relative to this case will be very much appreciated.

Fred S Brennen MD, Hesston Kan

ANSWER—The description given lacks several details that would be helpful in making a tentative diagnosis. The author of the query does not state whether the color of the eruption fades on pressure, as does the color of an inflammation, or persists under pressure, as is the case when the redness is due to a deposit of blood. Mention of the frequency and duration of the attacks would also be of assistance. Acute attacks of a vivid eruption which on fading passes through the changes characteristic of a bruise suggests erythema multiforme. Itching is not a common accompaniment of erythema multiforme but might occur in the form of the disease which has features of urticaria. Purpura is common in this disease, but erythema multiforme confined to the lower extremities in successive attacks over four years would be unusual.

The involvement of the lower extremities progressing slowly upward and the brown left on fading are also somewhat suggestive of acrodermatitis atrophicans but the latter disease is not characterized by acute attacks, progressing slowly without subjective symptoms.

Assuming that the doctor's observation and reasoning as to the cause of the itching are correct, one must think of the wide limits of the etiology of the purpuras. Musser and Wintrobe in the *Tice System of Medicine* (Hagerstown, Md., W F Prior Company, 1933, volume 6, p. 930) present a good outline and R. R. Kracke's article on the Diagnosis and Treatment

of the Purpuric Diseases (*South M J* 34 56 [Jan] 1941) will be found of value Kugelmann (Vitamin P in Vascular Purpura, *THE JOURNAL*, Aug 17, 1940, p 519) offers a method of treatment helpful in certain cases The same is true of the article of Peck and Rosenthal on the effect of moccasin snake venom in hemorrhagic conditions (*ibid*, March 30 1935 p 1066), and there are many others

MEASURING BLOOD CIRCULATION

To the Editor—An outline of the best practical means of determining total blood volume in man is desired Will you supply this information please?

Gail K Ridsperger, MD, Warren Pa

ANSWER—Total blood volume is not measurable in life in man, but the amount in actual circulation can be

The measurement of the circulating blood volume requires the estimation of the plasma volume and the determination of the hematocrit

Plasma volume is determined by measuring the dilution of a given amount of dye injected intravenously Samples of the blood are drawn after sufficient time for mixing of the dye in the blood stream has elapsed and the concentration of the dye in the plasma determined The degree of dilution of the dye can be considered an index of the circulating plasma volume Conversion of this figure into circulating blood volume can be affected by use of the formula

$$\text{Circulating Blood Volume} = \frac{\text{Circulating Plasma Volume}}{100 - \text{Hematocrit}}$$

The measurement of the dye concentration in the plasma can be determined by chemical extraction or preferably colorimetrically Numerous dyes have been used, but most of these have disadvantages such as rapid destruction or elimination of the dye within the period required for mixing, or passage through the capillary walls into the tissue spaces The development of the dye T-1824, which stays within the vascular system, has reduced these errors to a minimum The lot of dye must be standardized by measuring the light absorption of various dilutions of the dye in plasma In this way a reference chart may be prepared with which the plasma samples to be measured may be directly compared

A number of instruments are on the market which will measure the light transmitted by a sample The simple colorimeter is usually not sufficiently accurate since it does not discriminate the color of the dye adequately from other colors, thus introducing errors The spectrophotometer is an instrument which can be set at a particular wavelength and the absorption at this wavelength measured, but handling of this machine requires special techniques and it is not available in most clinical laboratories The photoelectric colorimeter has been adapted for use in plasma volume determinations by the use of a filter which allows light with wavelengths in the region of 620 millimicrons to pass A microattachment is also available which enables the worker to use small quantities of plasma

Further details of this method may be found in the following articles

- Gibson J G, 2d and Evelyn H A Clinical Studies of the Blood Volume *J Clin Investigation* 17 153 (March) 1938

DERMATITIS OF SCALP AND PERMANENT WAVE SOLUTIONS

To the Editor—A woman aged 53 stated that she had pruritus of the scalp with subsequent loss of hair and an erythematous macular rash involving the scalp face and trunk Her temperature rose to 102 F and there were orthralgias The work up revealed a mild secondary anemia and a leukopenia of 4 000 with a normal differential count Her symptoms persist and it is felt that a compound applied to the hair and scalp prior to the application of the waving machine may be responsible for her illness Would you be good enough to inform me of the possible agents which may be so used and which may cause such a syndrome to occur?

Herman L Jacobius MD New York

ANSWER—Before a permanent wave is given, the hair is softened by the use of a solution containing an alkali, usually ammonia, potassium carbonate or borax The solution also contains a gum which helps to stiffen the curls and make them last longer Tragacanth, acacia, psyllium seed, karaya gum or chondrus are commonly used for this purpose These are the ingredients most likely to cause sensitization of the skin and dermatitis Of these, karaya gum has been found the most frequent offender

The proper procedure would be to obtain from the hair-dresser a small amount of the lotion used in the case described and, when the skin eruption has cleared sufficiently to make it

safe, to make a patch test with the lotion, using a single drop on a minute piece of cotton or gauze, covered by a square of cellophane and fastened with adhesive tape In a case in which there is a possibility of sensitization to gums it might be wise to try the skin with adhesive tape alone at first, because the gums used in its manufacture may give a reaction If a positive patch test is obtained with the hair lotion, the manufacturer should be asked to furnish samples of the ingredients used in making it and these should be used for patch tests to determine just what is responsible

HYDROCHLORIC ACID ADMINISTRATION AND ULCER

To the Editor—When a person of middle age with achlorhydria takes a teaspoon of diluted hydrochloric acid with each meal is there any danger of bringing on oneself a gastric or duodenal ulcer because of the excessive intake of the acid? Is it safe to continue it for months or years?

MD Philadelphia

ANSWER—It has been shown by Shay and Gershon Cohen that 5 cc of diluted acid given with an Ewald meal to persons with achlorhydria produces little or no free acid in the gastric juice when tested with Topfer's reagent Schiffrin and Ivy state that ulceration in the gastrointestinal tract has never been produced in experimental animals by physiologic concentration of acid in the absence of pepsin A review of the literature fails to reveal any report of the production of gastric or duodenal ulcer by the therapeutic administration of diluted hydrochloric acid In view of this evidence it can be asserted that diluted hydrochloric acid in the ordinary therapeutic doses given at each meal may be taken for months and even years without fear of producing ulceration in the gastrointestinal tract It is advisable, however, to protect the teeth by using a glass drinking straw and by mildly alkaline mouth washes

GRID FOR EVALUATING PHYSICAL FITNESS

To the Editor—Can you give me any information as to the reliability of a grid for evaluating physical fitness by Norman C Wetzel MD? I have received the instruction manual and grid together with the reprint from *The Journal* March 22 1941 I shall be glad to have an opinion regarding the reliability of this grid for practical use

Frank Howard Richardson MD, Asheville N C

ANSWER—To estimate the reliability of a test of this nature it must be given to the same person twice, and the degree of association between the two sets of scores is determined by the computation of the coefficient of correlation If the test is reliable and the patient has not changed materially between its first and second application the two sets of scores will be nearly identical Wetzel's test probably has a high coefficient of reliability because the observational errors of simple measurements of height and weight should be slight, and objective errors, such as variants due to diurnal influences, are relatively small Wetzel does not calculate the statistical reliability of his test but he does examine into its validity This was tested by comparing grid scores with two other criteria of physical fitness and nutritive state (1) clinical appraisal and (2) reduction of data in the published literature to grid scores comparing these with the original rating distribution Both tests of validity indicate that the grid evaluates precisely what it purports to measure

The grid has been copyrighted by the author and his published description fails to include any reference to the data on which it is based Since there is a close relationship between height and weight during school life and the functions are strongly linear, strictly random samples of children of both sexes covering the specified age span may be used to establish the slope constant of this curve, which will have known probable errors Such traits as the height and weight of any population are variable Since the entire universe cannot be studied a fraction stands for the whole That it can do so rests on the laws of probability Thus the degree of the unreliability of any set of determinations may be measured as well as the scatter of the data

The grid appears to be a graphic representation of the regression line of the correlation surface between weight and height flanked by a series of "channels" which probably represent

multiples of the standard error of the line. The data given by Wetzel indicate that the observations about each isodevelopmental level line are distributed along a normal probability curve. This means that 68 per cent of the cases fall within $\pm 1 \sigma$ and 99.7 per cent within $\pm 3 \sigma$. When such a graph is used for critical comparisons, the chances of an individual falling outside $\pm 3 \sigma$ is quite small, $\frac{1}{370}$. If an individual deviates to such an extent, it is more probable that the cause is some abnormal factor rather than chance. The statistical method is the only practical one for the solution of the problem Wetzel has attacked.

HYPERTROPHY OF THYMUS

To the Editor—A girl aged 3 months was roentgenographed and I find a widening of the superior portion of the mediastinum. The child has been asymptomatic. Eight weeks ago she developed some cyanosis and some respiratory embarrassment. A roentgenogram at that time showed widening of the mediastinal shadow. She received three radiation treatments and the check plate that followed showed resolution of the widened superior portion of the mediastinum. This plate which was just taken is identical with the original plate taken eight weeks ago. The child is however apparently suffering no untoward effects from this recurrence if that is what the shadow indicates. My questions now are: 1. Is this due to thymic hypertrophy? 2. What should be done regarding further treatment since the reappearance of the shadow with no symptoms? 3. What is the usual course of thymic hypertrophy and what is the prognosis?

Michael H. Perlman, M.D., Hays, Kan.

ANSWER—The subject of hypertrophy of the thymus gland in infancy has today reached an impasse between that part of the profession which believes it to be clinically significant and the larger group, members of which believe that an enlarged thymus gland rarely causes symptoms. The latter feel that only in those cases in which the enlarged mediastinal shadow is due to a particularly broad and thickened thymus or to a thymoma are the pressure symptoms relieved by roentgen therapy. To answer the specific inquiries:

1. The respiratory embarrassment and cyanosis were probably not due to the thymic hypertrophy.

2. There does not seem to be any valid reason why the child should be treated further, especially in the absence of symptoms.

3. The enlarged mediastinal shadow gradually decreases in size unless a thymoma is present. The prognosis is good if the symptoms were on the basis of an enlarged thymus.

RADIUM FOR OFFICE PRACTICE OF OTOLARYNGOLOGY

To the Editor—I am contemplating buying radium enough to do the ordinary work that comes in to any eye, ear, nose and throat office. How much should I get and where would you suggest that I buy this?

Charles E. Gillespie, M.D., Seymour, Ind.

ANSWER—The conditions in the eye, ear, nose and throat requiring radium treatment that can be carried out in the office are so few and the use of radium with its attendant dangers is so specialized that it is rarely advisable for a physician to attempt to have his own supply of radium for this purpose. As a rule therapy either with radium or with high voltage roentgen rays should be entrusted to radiologists who have had the special training required for the safe and effective use of this treatment.

Radium may be secured from the Radium Chemical Corporation of America, New York. A total of 50 mg. in ten platinum needles of 5 mg. each should suffice, with a copper tube in which the needles may be placed for use in the nasal passages and with a monel metal box in which the needles may be placed for contact therapy on the skin.

OCCUPATIONAL EXPOSURE TO CITRIC ACID

To the Editor—Men working in a chemical plant making citric acid have complained of bad teeth. The impression is that the citric acid inhaled in dust form causes deterioration of teeth, softening of enamel and some gingivitis. Is there any specific information on the subject? Would an alkaline mouth wash such as solution of sodium bicarbonate be of benefit?

A. A. Bersin, M.D., Brooklyn.

ANSWER—It is difficult to evaluate the effects of occupational exposures without a careful dental record previous to the particular employment. Citric acid being a relatively weak acid is not likely to cause decalcification of the enamel of the teeth as do nitric and hydrochloric acid. However, prolonged exposure might eventually cause decalcification. It is more likely that citric acid dust, like other dusts, will produce its harmful effect through irritation of the soft tissues and abnormal wear of the hard tissues by physical rather than chemical action. The harmful effects can be better prevented by the wearing of masks rather than by the use of alkaline mouth washes.

TIC DOULOUREUX

To the Editor—In the *Journal of the American Dental Association* (27:507 [April] 1940) I saw an article by T. A. Hardgrove, DDS, entitled "Tic Douloureux: Etiology, Accurate Diagnosis and Treatment by the Use of Typhoid Vaccine." I should like to know what the opinion of the medical profession in general is as to the efficacy of this treatment and if it is being used at the present time I should appreciate an outline of the procedure in carrying out the treatment.

R. H. Hackler, M.D., Washington, N.C.

ANSWER—It is hardly believable to find in today's medical literature an article as the one entitled "Tic Douloureux: Etiology, Accurate Diagnosis and Treatment by the Use of Typhoid Vaccine." The article reveals ignorance of neurology, of the symptomatology of trigeminal neuralgia and of its voluminous literature. The etiology and pathology of this disease are yet unknown to the neurologist and neuropathologist. To call it but an aftermath of typhoid invasion or infection is just as ridiculous as to call it a complication of syphilis or of a respiratory infection. In reviewing the last 50 cases in a series of over 400 cases of major trigeminal neuralgia only 2 patients had a history of typhoid, 1 thirty years and the other forty-one years before the onset of the neuralgia. But a great number of the patients had all their teeth extracted by dental surgeons who did not recognize trigeminal neuralgia. The author, however, writes that its cause never lies in the teeth and the fact that typhoid is a systemic invasion or infection explains why this is true. He reports 11 cases treated by immunization with typhoid vaccine over a period of a year or fifteen months and claims to have obtained complete relief of pain and later of the tic or jerk.

There is only one permanent treatment actually known for true trigeminal neuralgia and that is the section of the pain carrying fibers, preferably central to the gasserian ganglion.

BASLE NOMINA ANATOMICA

To the Editor—Could you furnish any information about any publications giving the modifications of the Basle Nomina Anatomica as adopted by the Convention of the Anatomical Society of Great Britain and Ireland at Birmingham in 1933? I have a copy of F. Kopsch, *Nomina Anatomica*, giving the Jena modifications of the BNA of 1918 and 1935. I also have a late edition of Gray and Cunningham (seventh edition, 1937) which gives some but not all the names of the Birmingham revision.

M.D., New York.

ANSWER—The British Revision of the Basle Nomina Anatomica as approved by the Anatomical Society of Great Britain and Ireland is rather a new nomenclature than a revision. It was printed for the Anatomical Society by Robert Macchese & Co. at the University Press, Glasgow, in 1933. It was not widely distributed and it is doubtful whether any copies can be bought in the United States. It can doubtless be purchased from the Glasgow University Press.

The Glossary of Cunningham's *Anatomy*, Seventh Edition, 1937, states that terms altered or added in the British Revision of the BNA are listed in the first of their four columns. Presumably this is a complete list of such alterations. (It runs through thirty pages, and the printer indicates that it is complete for alterations.)

PLASMA TRANSFUSION NOT INDICATED FOR DIABETIC ACIDOSIS

To the Editor—Has plasma proved of value in the treatment of circulatory failure accompanying diabetic acidosis?

M.D., Virginia.

ANSWER—The circulatory failure accompanying diabetic acidosis seems to be due to dehydration and loss of electrolytes. The primary need in diabetic coma is for insulin in sufficient amounts. The second essential is the use of isotonic solution of sodium chloride in adequate quantities. Concentration of the blood is characteristic of diabetic acidosis rather than loss of blood or loss of plasma protein. Therefore replacement of water and electrolytes is needed and not plasma. Where there is reason to believe that loss of blood protein has occurred either by transudation into the tissues, by hemorrhage or by reason of some toxic complication, there would exist special indication for the use of blood plasma. Since patients with diabetic coma frequently prove to have some infectious complication, it is well to bear in mind the possible advantage of transfusion with plasma or whole blood under such conditions. It is true that frequently in diabetic coma blood is found in the stomach, but it is seldom excessive. Its presence has been thought due to diapedesis from stretching of the walls of the stomach. If this transudate of blood occurred in the entire alimentary tract as in the stomach then the occasion for use of plasma blood would be present but apparently so far this has not been noted.

THE REMOVAL OF METALLIC FOREIGN BODIES FROM THE EYEBALL AND FROM THE ORBIT

EDMUND B. SPAETH, M.D.

1311 ADELPHIUM

The satisfactory disposal of cases of metallic foreign bodies in the globe and/or in the orbit presents two definite problems. The first of these is the diagnosis of the presence of a foreign body, a determination of its probable structure or alloy mixture and its accurate localization, the second the surgical procedure to be used which is best for the removal of the foreign body under consideration. In considering extraocular foreign bodies, x-ray plates are the ophthalmologist's single greatest diagnostic aid. Magnetic probes will be used more and more in the near future, but only under circumstances of great stress and with time and equipment limitations. A third might be of importance at rare times though this will not always be under one's control, i.e. when is it wiser not to attempt the removal of a certain foreign body under treatment? The first two of these three are my immediate direct concern.

A rather logical controversy exists between ophthalmologists and roentgenologists as to the relative value of stereoscopic x-ray films and of films taken in a single plane—horizontal or vertical as the demand may be—but all exposures at a different angle. Some roentgenologists are quite frank in stating that stereoscopic plates are inferior in their diagnostic value while others consider the reverse of this fact. Actually, both means are important though not always comparably so in a single case. Furthermore, the ophthalmologist is more capable of deciding which of the two is to be used in any given case under consideration.

Figure 1 presents the side view in a case wherein lateral views taken at right angles to each other in horizontal and in vertical planes were of greatest value. The task of deciding which of these foreign bodies lie inside and which outside the orbit and which inside of the globe is almost similar in extent of computations necessary to that needed in studying an astronomical photographic plate. The flat films taken at the varying angles in the two planes, however, showed rotation movements of the foreign bodies in relationship to each other and to the various fixed anatomic landmarks. It was thus possible to decide that of the four bodies in the region of the orbit (fig. 2) *A* lay intraorbital immediately behind the rim of the orbit, *B* within the orbit at the medial angle and the roof of the orbit and *C* and *D* in close relationship to each

other below the zygoma and within the temporal fossa. The deformation of the various shot (*E* and *F* as compared with *G*, *C* and *D*) show well the lines of fire resulting in the deformity and fragmentation of the first two (fig. 3). This has not occurred in the last three.

Apparently *G* struck the bones of the skull at a very tangential angle, *E* became fragmented against the solid bones of the frontal plate and the *F*s were deformed because of their almost perpendicular incidence. *A*, *B*, *C* and *D* show but little change in shape because of their entry into the softer tissues of the orbit or the thick temporal muscle which cushioned the blow or force of impact. It is quite evident that in this case stereoscopic films would have been of much less value for orbital localization.

Figure 4 illustrates another case, however, in which anteroposterior stereoscopic views were of the greatest assistance. The foreign body lies, very probably, partly in and partly out of the orbit. Removal might be done through the temporal fossa or from an orbital approach, or a transcranial approach might even be considered (similar to a Naffziger orbital decompression), this would be considered more seriously perhaps in cases in which the foreign body lies more superior and posterior. The patient was a World War I victim, extraction of the foreign body, delayed for years, was made necessary because of increasingly severe head pains. The patient had lost his opposite eye. The remaining eye had considerable traumatic retinal and choroidal disturbance but still had good central visual acuity. The patient was operated on successfully through the external route by a Shugrue bone resection, on the basis of the stereoscopic roentgenograms. A Kronlein resection, necessary otherwise, would have meant more extensive surgery with no better and perhaps even poorer results. The position of the foreign body would have limited the external bone flap, with danger to an eye already damaged by the original injury, also the degree of scar tissue in the orbit would have made that procedure rather more formidable.

A further utilization of angled plates, this time in the vertical position, is necessary for the study of parallax. Figure 7 illustrates such an instance. A mine explosion victim had one remaining foreign body still retained, its position was uncertain. Here *A* shows the position of the foreign body, the marker being in exact contact with the apex of the cornea and 26 mm from the foreign body, *B* is the same with the patient looking up 45 degrees and *C* with the patient looking down 45 degrees. The diagrammatic sketch (fig. 5) actually superimposes these three films and the movement of the foreign body. In 45 degrees downward rotating 1 moves only to 2, and with the same amount of upward rotation the foreign body moves to 3. Charting these movements in relation to a 24 mm eye, one can see that while there has been movement of the foreign body it is

insufficient to indicate that the particle is in the eye or even in the sclera but that it must be extraocular and that the movement demonstrated must be due to muscular action. This conclusion should be sufficient.

In the first of these 3 cases used as illustrations, the first of the horizontal plates was taken in the line of fire

Fig 1—Results of a hunting accident

and the second at a right angle to this. A simple sketch, as shown, will thus permit exact localization. In the second case, the size of the shell fragment and its relationship to the sphenoidal surface of the lateral wall of the orbit made me feel that stereoscopic plates would localize the fragment well and indicate the best route for extraction. In the third case further surgical procedures were avoided in an eye already seriously jeopardized by previous necessary operations. Without further surgery the eye had a very good chance for recovery, and a retained foreign body would lessen that

Fig 2—Diagrammatic sketch showing the position of the various shot indicated with letters for discussion in the text

possibility to a tremendous degree. The further progress of that case confirmed our observations and the prognosis just expressed.

At this moment, there is nothing to add as to the established value of the triangulation method for the localization of intraocular foreign bodies. As a matter of fact, with the present method of coordinates and of master charts, even that personal equation of excel-

lence of or the lack of this in the roentgenologist taking the pictures is hardly significant. Accurate measurements and positioning and a 24 mm eye are the only essentials. Many small foreign bodies, especially in the case of multiple foreign bodies, are not always within the globe. They may lie, instead, either on or in the sclera. Other larger foreign bodies may have perforated the globe, traversed the vitreous chamber and again have passed through the sclera to lie external to this. In all eyes in which there is any doubt, air should be injected into Tenon's capsule and then roentgenograms should again be taken and studied. These roentgenograms are to be made at several angles (an exactly similar principle as that mentioned in regard to the first case referred to) to separate the shadow of the foreign body from that of the space of Tenon. The layer of air below Tenon's capsule forms a band of dissimilarity which may be plainly visualized in contrast to the denser bony tissues of the orbit. By making pictures from various angles, the relation of the foreign body particle to the capsule may be accurately demonstrated. The procedure is wholly without danger and

Fig 3—Diagrammatic sketch to illustrate the estimated line of fire the reason for deformity and fragmentation of some of the shot and the localization as indicated by angled flat views

its potential value is great. Recently, in a case of nonmagnetic metallic foreign body, probably an aluminum alloy, it was the deciding factor in choosing the surgery necessary.

Radiopaque fixed corneal and scleral landmarks, to be used in localization, are rather common. Many different types have been presented from time to time. Excluding iodized poppyseed oil, all of them are in principle an openwork wire cage which fits over the cornea and on the scleral shoulder. The great difficulty with most is their inaccurate fit, in that scleral and corneal curves vary sufficiently within the normal limits to make errors of 2 and even 3 mm common. In the surgical removal of nonmagnetic metallic foreign bodies, one must be more accurate than this if satisfactory surgery is to be done. Their greatest value is not to augment localization. This can be done with full satisfaction by the Sweet system, certainly with intraocular particles, and, within certain fair limits, also for extraocular particles. Instead, they furnish fixed external surface landmarks from which exact measurements can be made to permit the removal of non-

magnetic foreign bodies. Iodized poppyseed oil itself can be floated behind a Koeppé contact lens, giving a perfect fixed radiopaque landmark for accurate localization of foreign bodies lying in or at the anterior chamber angle, at the root of the iris and in the ciliary body. It has been the means of deciding the exact position of minute metallic particles.

Figure 6 shows an instance of extraocular foreign body. This is an instance of foreign body cyst with a draining fistula, figure 8 shows the x-ray appearance of the foreign body and figure 9 shows the appearance of the cyst after injections with iodized oil. Figure 10 shows by known measurements the extent of the canthal angles, the cul-de-sacs and the position of the cornea. Removal of the foreign body is facilitated by these various localization methods.

For an intraocular foreign body a small number of true circular silver rings are necessary, one each of about 6 mm, 14 mm, 18 mm and 20 mm in diameter, and perhaps intermediate sizes. After localization, the one nearest in size to the position of the foreign body, judged on the globe equatorially, is firmly sutured to the conjunctiva-sclera, and a second smaller one similarly to rim the approximate position of the particle.

Fig 4—Sketches to show the position of a metallic foreign body as it lay *a* from the side *b* a front view, and *c* a (schematic) view from above. Stereoscopic films are of greatest value in this type of case.

These are then checked by exact anteroposterior films. With these rings, of a known size and placed at known distances from the limbus, it is a simple matter to outline, with exactness, a hinged sclerotomy incision for any exploratory incision desired.

A case to illustrate this last technic appears in figure 11. The patient was a ballistics expert and the accident incident to his investigation of a faulty firing mechanism on a revolver. After recovery from the linear extraction, because of a traumatic cataract, one could see the portion of the foreign body buried in the retina and choroid within a mass of exudate wholly inaccessible to the endoscope because of its lack of visibility, and quite unsuited to the use of the biplane fluoroscope. This might have resulted in a fatal tearing off of the retina and choroid. The foreign body was a scale shape portion of a brass cartridge case. After completion of the x-ray studies the rings were sutured in place, as shown in figure 12. Careful measurements were made on the sclera, according to the charts, the smaller of the two rings was marked with gentian violet and the ring removed. The conjunctiva was then incised, the inferior rectus detached temporarily and a hinged flap formed in the sclera, the hinge, however, lying posteriorly. The choroid was detached from the

flap of this with an iris spatula and the glistening choroid carefully investigated with a telescopic magnifier. Palpation of the choroid with an iris spatula revealed the foreign body, exactly at the site estimated. This, with the choroid, was grasped with an iris forceps and, following a clean snip by the Barraquer forceps-scissors, the particle was removed with ease. A tiny bead of vitreous presented, so, after the flap was closed

Fig 5—Diagrammatic sketch of foreign body shown roentgenographically in figure 7.

with 6-0 plain catgut, the sclerotomy incision was rimmed with Walker needles. The patient recovered with 6/6 aphakia correction and with a full field of vision. This one case, described in some detail, is sufficient to illustrate the general technic. The technic tends to become more difficult and complicated and less useful, the more posteriorward the position of the foreign body.

The biplane fluoroscope has two general applications—the first quite proper and of undoubted value and the second occasionally necessary, even compulsory, but always fraught with danger to the integrity of the eye.

As to the first of these, in the necessary removal of retrobulbar, deeply embedded, radiopaque foreign bodies the technic has no equal, in fact there is no alternative. The operation can be performed with careful dissection and with deliberation to a certain extent, interrupted and the patient moved into the fluoroscopic room and thereafter returned to the operating room for the resuturing of the detached muscles, for the closure of skin and conjunctival incisions and for the dressing. The exact removal of the particle demands accurate localization, a bit of gentleness in the use of grasping forceps and that detailed knowledge of the anatomy of the orbit which all who operate should have. The following case is quite illustrative.

A young mechanic was seen with a copper-bronze particle the size and shape of a deformed dime deep in the orbit superiorly and probably entangled in the muscle cone. The patient had almost complete paralysis of the superior rectus, the levator palpebrae superioris and the superior oblique muscle, exophthalmos, and considerable post-traumatic and post-operative inflammatory reaction, for two unsuccessful attempts at removal had already been made. The vision

Fig 6—Foreign body cyst with external fistula cyst and foreign body as shown by subsequent injection of iodized poppyseed oil to lie wholly intraorbital.

was still unimpaired. If the earlier unsuccessful operation had not already damaged, beyond hope of recovery, the oculomotor neuromuscular mechanism, early removal was doubly imperative. Extraction with the biplane fluoroscope was uneventfully successful and did not add further anatomic damage to that already present.

The second indication is that in connection with the removal of an intraocular, radiopaque, nonmagnetic foreign body not attached to or in close proximity to the retina, with vitreous clarity disturbed by hemorrhage or exudate. The latter prevents the use of the endoscope, and one dare not attempt the removal of such a foreign body by means of a sclerotomy flap unless the particle can be grasped with exactness through the sclerotomy opening. In such cases one must use a biplane fluoroscope, knowing, however, that grave disorganization of the retina, choroid, vitreous or lens may result. This need not follow necessarily, but it does sufficiently often to make one unwilling to use the procedure for intraocular particles unless absolutely required. The various grasping forceps used for the endoscope are as valuable now as when used otherwise (fig. 13). Forceps that depend on their opening and

localization is not always necessary or possible, as the British have shown, in recent war surgery. The giant magnet is not only a therapeutic instrument but also of diagnostic value. Its value is not in an increased magnetic attraction but in its proportionately increased width of magnetic field. Because of this the degree of pull can be even further controlled and definitely affected by varying the distance between the patient and the tip of the magnet. For instance, when the giant magnet is used, and with an anterior route extraction, it is not good technic to use the giant magnet for removing the particle itself from the anterior chamber. The hand magnet is better for the completion of the operation. In the final analysis the giant magnet has its greatest value in the demand for a diffuse magnetic field, which permits and which needs variability, while the hand magnet has its only indication in cases in which the magnet tip can be applied directly or approximated to the foreign body at an interval no greater than 2 mm. This is a clinical proof of Lancaster's criteria for good magnets. "Unless a giant magnet will pull a tiny steel ball with a force over fifty times its weight at a distance of 20 mm, and unless a hand

Fig. 7—Extraocular particle. A, marker at 26 mm distance; B, with patient looking up; C, with patient looking down.

closure by the conventional two-blade spring connection construction are limited in efficiency. The size of the sclerotomy controls the degree of forceps opening possible, as well as does the ease of the rotation of the instrument within the opening depend on the caliber of the grasping instrument.

One case, sufficiently satisfactory in end result to permit inclusion as an illustration, involved a brass brad removed from the ciliary body or its immediate neighborhood. Convalescence was a bit stormy, resulting in a cychtic or traumatic cataract and eventually a quiet eye. Enucleation was done years later because of recurrent iridocyclitis, which was reactivated by a minor traumatism. To be fair, however, other men, as Cross, have reported much better results with this form of surgery. Apparently, cases for the technic have not been wisely selected by me. Furthermore, in very recent years a biplane fluoroscope has not been especially accessible.

The literature relative to the use of giant and hand magnets is quite sufficient and needs no repetition. Lancaster's contributions are outstanding. Certain points can be emphasized here properly as being in keeping with this paper. Both giant and hand magnets have indications optimum for use, and one is not interchangeable with the other as an ideal procedure. Exact

magnet will pull a tiny steel ball in contact with its tip with a force over five thousand times its weight, they are not good magnets."

General rules can be laid down as to the selection of an anterior route extraction versus a transcleral extraction. The smaller the particle the more is the former indicated, the larger the more is the latter indicated. An intact lens should be left so, hence a damaged lens tends to demand an anterior route extraction and permit it for the larger fragments. Foreign bodies that have entered through the posterior segment of the sclera or which lie in the posterior portion of the globe should be extracted from the eye by the anterior route, all other factors permitting. If the point of entrance is well behind the ciliary zone and anterior to the equator, that extraction may be done through the point of entrance. The giant magnet can bring the foreign body toward this point of entrance for easy hand magnet removal. When the particle lies generally in the region of the equator on or in the retina and a posterior route removal is deemed wise, the sclerotomy for the extraction is to be done on the sclera at that spot closest to the position of the particle, and the hand magnet should be used for the extraction. Sclerotomy incisions and points of entrance should be rimmed with diathermy needles to guard against a later

retinal separation. Foreign bodies suspended in the vitreous usually need the giant magnet for extraction. Early surgery is perhaps the greatest factor in these cases unless the foreign body lies wholly within the lens. When only a hand magnet is available accurate localization is absolutely necessary. With the giant

Fig 8—Lateral view showing foreign body

magnet this is less important. A permanent magnet has but little value except with foreign bodies in the anterior chamber, and even here their magnetic attraction force is so slight as to be of doubtful value. The anterior route extraction has as its purpose the prevention of further operation damage. Hence, in its use one must prevent incarceration of the foreign body in the iris or the

ciliary body and damage to an intact lens. When metallic foreign bodies are removed from the anterior chamber it is important that the corneal incision be perpendicular to the cornea and not obliquely placed at the angle, for the latter will form a shelf, making difficult the removal of a flat or scale shaped particle. After a keratome incision and with magnetic pull, when the iris prolapses because of an incarcerated foreign body, a single meridional forceps-scissors iridotomy will permit the removal of the particle and the replacement of the iris.

Usually it is useless to work with any type of magnet head except the blunt tip with the broadest magnetic field; similarly, the introduction of forceps, probes,

Fig 9—A, vertical view showing appearance after injection of iodized oil, B, lateral view (A was printed from the reverse of the films through error)

scissors and similar instruments into the eye, these in contact with the magnet core, is of little value as far as magnetic pull is concerned. This also may be the cause for considerable damage to the retina and the choroid. One must remember that the hand magnet is a contact instrument and that the giant magnet alone

permits varied manipulations at different angles of attraction for dislodging an incarcerated particle, for guiding a metallic particle around the posterior surface of the lens and for diagnostic purposes. Further, it is wise to remember that all foreign bodies, when magnetically attracted, move with their long axis parallel to the pull of the magnet—never at any great angle from this—and even this deviation from parallelism is only mechanical and due to the friction of structures touching the foreign bodies during the extraction. Extraocular foreign bodies are similar in their individual demands, i.e. the giant magnet versus the hand type.

The ocular endoscope, and especially Thorpe's model, is the last item to be here considered. Its use has been proved an ideal procedure for the removal of intraocular nonmagnetic foreign bodies which lie free within the globe and are not incarcerated or entangled to any great extent in the retina, the choroid or the ciliary body. Furthermore, the vitreous chamber must be

Fig 10—Front view with injection of iodized oil also with corneal scleral marker in place to show the extent of the conjunctival fornices and the position of the cornea. In this view (printed from the reverse) one might think that the cyst lay in part extraorbital; this appearance however is due to the fact that the cyst lying in the soft tissues of the orbit and lid when filled with iodized oil passes over the internal canthus (see figure 7)

reasonably free from free hemorrhage and from gross vitreous opacities. Figure 13 illustrates the endoscope and several of the many varied grasping forceps available—these limited alone by the ingenuity of the surgeon. As a matter of fact, such forceps can and should be designed for individual cases, depending on the particle to be removed. One shown in the illustration is for removing a birdshot, another for a thorn and another for grasping a piece of glass. In some of these cases, the point of entrance of the foreign particle can be used also for the entrance incision of the endoscope. Naturally this depends on the size, the shape and the position of the entrance wound. Localization with the ophthalmoscope is usually adequate, though particles incarcerated in the ciliary body and in the zonula and the suspensory ligament of the lens could hardly be seen with this. If the entrance wound cannot be used, a fresh meridional incision must be made so that the grasping forceps can be approximated close to the foreign body, this incision need not traverse any

more vitreous than is absolutely necessary. It must be sufficiently large to permit the introduction of the endoscope as well as the removal of the particle held within the grasp of the forceps.

Practice in the use of this instrument is readily obtained by working with various shapes and sizes of

Fig. 11—Diagrammatic sketch illustrating the position of the foreign body.

foreign bodies placed in a small pill box, covered about the size of the globe. Holes, to simulate the sclerotomy incision are made at various positions, in the angles and on the sides and the cover of the box. Visibility within the eye depends on the clarity of the vitreous—so this is an outstanding criterion as to indications for endoscopy. If one cannot see the

particle to be removed, the biplane fluoroscope may be the only alternative available.

Some practical points relative to this instrument, and learned by experience, are worth repeating. The endoscope should be introduced slowly and deliberately, movements and angulations of the grasping forceps and telescope end should be no more than necessary, one should depend on careful preoperative planning to minimize damage to the vitreous, and the forceps should be advanced very slowly and gently to prevent damage to the delicate retina. An assistant must fix the eye adequately and watch at the same time to prevent too deep penetration of the endoscope into the vitreous chamber. Vitreous will not prolapse while the instru-

Fig. 12—The preoperative position of the silver rings. One can see the position for the sclerotomy within the smaller of the two rings.

ment is in use unless the wound of entrance is large or must be made large because of the size of the particle. The structure of the vitreous, bands of infiltration and exudates may make it difficult to grasp a foreign body which is suspended free and not supported by incarceration in some structure. The foreign body is withdrawn with the endoscope, the eye of the operator never wavering from the eyepiece until the instrument is out of the eye. The final grasp, once obtained, on the foreign

body. After withdrawal of the forceps, the sclerotomy incision should be rimmed with diathermy needles, as was mentioned for the transcleral posterior route magnet extraction. The vortex veins must be spared regardless of the position of the foreign body. My experience with the instrument has been limited (perhaps fortunately) though sufficient to agree wholly with Thorpe's claims relative to the value of the instrument.

CONCLUSIONS

The extraction of magnetic and nonmagnetic foreign bodies from the globe and the orbit from personal experiences is considered to evaluate some of the rather significant and important procedures at one's command. They include the following:

- 1 The great and important possibilities of roentgenograms, frequently not used adequately, both as to flat angled views and as to stereoscopic views.
- 2 The use of air injections into Tenon's capsule for more accurate localization of extraocular particles.
- 3 The use of radiopaque appliances for localization, but especially as an aid to the extraction of nonmagnetic foreign bodies, with a flap sclerotomy.

11, 12, 13—The Thorpe ophthalmic endoscope and several forceps to be used with this one for bird shot, one for a scale or chip, another for a sliver or thorn. (Slightly reduced.)

- 4 The use of and the indications for the biplane fluoroscope.

- 5 A consideration of certain important factors in the use of magnets, diagnostic and therapeutic.

- 6 Indications for, and the use of, the endoscope.

1930 Chestnut Street

ABSTRACT OF DISCUSSION

DR EDWARD STIEREN, Pittsburgh. I do not subscribe to the statement that a foreign body in the vitreous means potentially a lost eye. The vitreous body is more or less of a mystery. Duke-Elder considers it a gel. My experience is based on forty-five years of practicing ophthalmology in an industrial community with a record of more than eight hundred extractions of foreign bodies from within the eye. Long ago I noticed that if the vitreous was much disturbed or a fourth of its bulk was lost it resulted in a sick eye, an eye that was not inflamed or infected but marked by lack of the beautiful transparency of the vitreous, so that the fundus would appear as though looked at through a fog. These eyes usually develop minus tension and go into decline, a great many ending in phthisis bulbi. In removing foreign bodies from the vitreous I feel that it is a great mistake to plunge any instrument, such as a cataract knife, in making the scleral section or introducing the various tips that come with the hand magnet into the vitreous and stirring it up. Probably the accident happened about an hour

or two before and the wound of entrance is still open. The temptation is great to apply the magnet immediately. I advise against this for two reasons. The foreign body may not still be in the eye, it may have gone through into the orbit. We must know the size of the foreign body, as well as its location, before attempting removal. The same argument obtains against using the electromagnet as a diagnostic instrument, as a sideroscope. The foreign body may not be within the eye at all. If in the case of a recent injury it cannot be seen with the ophthalmoscope, the eye should be roentgenographed and the foreign body plotted. Then one knows just where the foreign body is, and its size. The sclerotomy is performed with gentle dissecting strokes until the choroid presents, and then a very delicate opening is made through the choroid. Then the tip of the magnet, either the oval or the cone shaped tip, is introduced into the lips of the wound, and only then should the current be turned on. The wound of entrance is misleading sometimes. A foreign body may be long, 4 or 5 mm, and very narrow, and maybe it has left a very small opening in the globe. But in being withdrawn with the magnet it may become lodged crosswise. Instead of tugging and pulling and trying forcibly to remove a large foreign body through an inadequate opening, it is much better surgery and less hard on the eye to have the opening accommodate the size of the foreign body. Dr Spaeth suggests a hinged flap. I have never tried that. I prefer a T shaped incision.

DR RAYMOND L. PFEIFFER, New York. Dr Spaeth has reviewed the mechanical and surgical aids which must be available to one seeing many cases of trauma of the eye. A great deal can be said on each of these aids, and one's experience with each does not always correspond with the degree of importance which Dr Spaeth has indicated. He rightly emphasizes the importance of meticulous x-ray work in the diagnosis and localization of intraocular foreign bodies. Many methods are available for this work, and the roentgenologist is most proficient with the method with which he is best acquainted. I have described a simple, inexpensive and accurate method which gives a meridional plotting easiest for the surgeon to utilize in the operating room. This method employs a contact lens similar to the Zeiss lens, which was adapted to the localization of foreign bodies in the eye by Comberg in 1928. After the lens is placed on the injured eye, posteroanterior and lateral films are made of the orbits, and lines are scratched directly on the films to indicate the meridian in which the body lies, its distance out from the anteroposterior axis of the eyeball in this meridian and its distance back from the limbus of the cornea. The measurements, minus correction factors due to the magnified distortion which occurs in all x-ray films, are transferred to a specially prepared drawing, which shows the eye in front and lateral views enlarged three times for accuracy of plotting. This method is simple, rapid in operation and accurate. It is impossible to make a significant error with it. One need not fear placing the lens on severely injured eyes if a few drops of a local anesthetic such as pontocaine is used. This method is especially well adapted to field work. Nine years of experience in a busy eye hospital with this method has been most convincing. Soft tissue films or bone free films, first advocated by Vogt, should be made in every case of suspected intraocular foreign body. These films are easily prepared and are capable of revealing the most minute foreign bodies of any density greater than that of the tissues. Glass fragments may be overlooked with them. They may reveal bodies which can be overlooked in ordinary films. Their usefulness, however, is limited to the anterior segment. In ordinary cases of metallic foreign body they offer a check on the localization achieved by other methods and reveal the shape and suggest the character of the foreign body.

DR HARVEY E. THORPE, Pittsburgh. It is important to make a careful slit lamp examination to determine whether there has been a penetration of the cornea, sclera, the iris or the lens. An x-ray examination of the eye is essential. The method of x-ray localization with air injection in Tenon's capsule described by Dr Spaeth should be valuable. I use

Sweet's method of localization and with it frequently combine Comberg's method. I now use a plastic contact lens instead of the glass Comberg lens. Instead of the lead markers, which are difficult to insert into the plastic lenses, I use small platinum wire markers, which can be placed accurately into the plastic contact lens. The contact lens method of localization of intraocular foreign bodies can be combined with a stereoscopic technique. This enables the ophthalmic surgeon to view the eyeball either by the air injection method or, possibly easier, by the method of the contact lens in stereofilm. I cannot stress too strongly the use of the stereofilm and accurate localization, because only then does one know where to make the incision for the removal of the foreign body. The use of the ocular endoscope is a protean procedure. I do not recommend it in the hands of some one who has not previously acquired practice on many animal eyes. It is essential to practice first with the operating end of the endoscope inserted into a little hollow sphere (1 inch in diameter). This should be followed by practice on animal eyes to acquaint oneself with an instrument that is guided only by monocular vision. Being prepared for this major procedure, one may now attempt the removal of non-magnetic foreign bodies from a nonbloody vitreous. I devised this instrument primarily for the removal of copper, lead or other nonmagnetic foreign bodies from the vitreous. It has been the general experience of ophthalmologists that a piece of copper in an eye meant enucleation of the globe. The use of the endoscope may save the globe and may even preserve sight. One is therefore justified in using the instrument. The endoscope measures 6 mm across. It is not introduced beyond the scleral incision, it is placed just within and between the lips of the scleral incision. The lips of the wound are held open by previously inserted scleral sutures. The assistant holds the operating end of the instrument to prevent its being shoved too deeply into the globe while the surgeon has his eye at the observing end of the endoscope. With the miniature electric bulb illuminated, only the minute tubular forceps (1.5 mm in diameter) is pushed down to the lead shot.

DR OSCAR WILKINSON, Washington, D. C. I wish to emphasize the importance of attempting to remove very small foreign bodies from the vitreous as soon as possible after the injury. When the foreign body is visible with the ophthalmoscope and one can use a hand magnet and determine, with the ophthalmoscope, whether it is magnetic or not, it facilitates matters very much more to do this early, before any inflammatory changes have taken place. Recently I deferred until the next morning the removal of a foreign body in the vitreous which was subject to magnetic influence, at which time there was no hemorrhage at all in the vitreous. The next morning, when I undertook its removal, the vitreous was full of hemorrhage and I could not find the foreign body without x-ray localization. The use of the hand magnet in removing smaller objects is superior to the larger magnet. With the larger magnet one sometimes gets the foreign body and the eye too. With reference to the scleral route, several years ago I heard Samuels discussing the effects of foreign bodies on the vitreous. His idea at that time was that a foreign body in the vitreous meant that the vitreous would be so altered and so mutilated that eventually the sight would be practically lost. If these minute foreign bodies are removed immediately, the prognosis is more often favorable. One saves a man's eye and gets practically no reaction afterward. I always use fulguration to prevent hemorrhages in making the scleral incision. When a patient comes into one's office with the history of an injury, practically always a penetrating wound will leave a lowered tension of the eyeball. It is a good plan to put one's finger on that eye, and if it is softer it is an indication that that eye has been perforated.

DR ELBERT S. SHERMAN, Newark, N. J. For the successful management of a case of intraocular foreign body proper equipment, experience and good judgment are important. For years there has been discussion as to whether it is safer to remove a piece of steel from the vitreous by the anterior route or through an incision in the sclera. In many cases, for well

known reasons, the anterior route should be chosen. In others, probably a small majority, the transscleral route is safer and easier. It has been alleged that detachment of the retina is a frequent sequel of removal by the posterior route. As I have shown (*Am J Ophth* 22 1368 [Dec] 1939) retinal detachment is not a necessary complication. In my experience it has occurred only once. This may be because most of the cases have been seen promptly and operation performed within twenty-four hours after the accident. Another important reason is that no instruments are permitted to enter the vitreous, and this vulnerable structure is disturbed as little as possible. If done early, before the eye has become inflamed or adhesions have formed the operation is easier and complications are less likely to occur. I have had no experience with the biplane fluoroscope but have been unfavorably impressed by the late results following its use. I agree with everything that Dr Stieren has said.

DR STIEREN. In a paper read before the American Ophthalmological Society in 1935 Jonas Friedenwald presented a diagrammatic drawing showing the arrangement of the sheets comprising the vitreous. It illustrates what happens when one introduces anything into the vitreous chamber. Friedenwald does not say so, but it seems to me that this viscous material, the fluid between these sheets if it is not lymph, must act as lymph and is intended for the nourishment of the inside of the eye. When one destroys these sheets one destroys the channels.

DR EDMUND B SPAETH, Philadelphia. Dr Pfeiffer has brought to our attention the importance of the x-rays in the handling of these cases. Relative to Dr Sherman's statement there is now a patient in the hospital who emphasizes this matter of retinal detachment. A foreign body perforated the sclera 10 or 12 mm behind the limbus. The patient on admission to the hospital had a trifoliate retinal tear and at the end of three days a complete retinal detachment. The patient was treated from the time of his admission to the hospital with absolute quiet and pinhole glass but in spite of this detachment occurred. With regard to the use of the endoscope it is absolutely necessary that these cases be taken care of very early, otherwise changes which occur in and of the vitreous make it impossible even to grasp the foreign body with the endoscope forceps, because of the infiltration and condensation of the vitreous encapsulating that foreign body. The paper in its entirety covers certain points most important about magnets. The giant magnet and the hand magnet are not interchangeable, nor is it permissible to consider the anterior and posterior routes as not having maximum optimum indications for use. The giant magnet is a magnet with a wide magnetic field, which can be well controlled and does not demand accurate foreign body localization. The British in their recent war surgery have demonstrated that to us. The hand magnet is a contact magnet and if one cannot approximate the foreign body with a minimum of 2 mm, there is no use whatever in trying even to use the hand magnet. The indications for anterior and posterior route extraction have been covered in the paper.

Irrational Fears—States of fear are not all "rational" and based on objective realities of the moment. It is one of the calamities of modern life that not a few individuals of adult age are harassed by irrational fears the source of which is to them mysterious and incomprehensible. There is no manifestly threatening situation in the environment, yet they feel afraid. They cannot escape from vague consuming fears that take possession of consciousness, disrupting the harmony of the personality, dissipating nervous energy and destroying peace of mind. It is this subjective fear that is at the foundation of the majority of the so-called anxiety neuroses in ordinary civilian life. Experience has made it clear that many of these subjective fears can be traced to disturbing impressions determinative of emotional imbalance in the early years of life, whilst mind and brain were plastic and the future life pattern was in process of formation—MacDonald, J. H. *Fear Neuroses, from War and the Doctor*, edited by J. M. Mackintosh, M.D., Baltimore: William Wood & Co., 1942.

EFFECT OF GASTRIC RESECTION ON GASTRIC ACIDITY

Early in the war Willcox¹ reported that, of 41 soldiers evacuated from France and complaining of dyspepsia, 19 had duodenal ulcers and 7 had gastric ulcers. He expressed the belief that the ulcer had existed in most cases prior to enlistment and that conditions in the service had caused a relapse. The etiologic factors for exacerbation or recurrence of symptoms he listed as an increased use of tobacco, alteration of diet, dental deficiencies and familial background. He was unable to relate the high incidence of ulcer to neurogenic factors and felt that ulcer did not develop in men entirely healthy prior to enlistment in the services. Morris later reported that 143 men in a group of 500 soldiers complaining of dyspepsia had duodenal ulcer. Payne and Newman² made an interim report on dyspepsia in the British army up to December 1940. From the period of dispatch of the British Expeditionary Force until the invasion of France, 12.5 to 14 per cent of all men evacuated to England had a diagnosis of gastric or duodenal ulcer. This was much higher than the incidence of effort syndrome, which has received much more attention and publicity. Investigation by them disclosed that 92 per cent of the men had had ulcer symptoms before enlistment, which had become exacerbated after enlistment. In 40 per cent of the cases the age was under 25 years.

Saffley⁴ more or less summarized the situation in his study among the various military hospitals in England. Three hundred and twenty soldiers who had dyspepsia were studied roentgenographically by him, 111, or 35 per cent, had duodenal ulcers, and only 13 had gastric ulcers. His conclusion was (to paraphrase Napoleon) "In marching on its stomach the army of today apparently produces considerable wear and tear."

Cases of duodenal ulcer are frequently encountered in the medical military services of our own armed forces. The proper disposition of these cases is difficult in the military hospital, which has demands on its beds and its personnel. Most of the patients who have active peptic ulcers ultimately are surveyed from the service. The same fate awaits these men, according to Saffley,

in the British army. The problem is one which cannot be discussed here, but we should like to report such a case which came under our observation at the United States Naval Hospital, Philadelphia.

REPORT OF CASES

CASE 1—A veteran, white, aged 25, was admitted to the Naval Hospital for treatment of an intractable duodenal ulcer. He had been discharged from the Army by reason of medical survey in June 1941 after medical treatment of his duodenal ulcer. He stated that his ulcer symptoms had begun in March 1941, eight months after induction into the Army. In October 1941 he was admitted to the Naval Hospital as a veteran, complaining of moderate but continuous epigastric distress unrelieved by the usual methods. Two courses of modified Sippy type of diet over a period of several months afforded only slight relief. Roentgenologic studies each time revealed the presence of a duodenal ulcer, and analysis of the gastric contents revealed free hydrochloric acid in the stomach ranging up to 65 units. Because of the intractable pain and the failure of medical management to provide relief, as well as the youth of the patient and the moderate elevation of acidity, surgical treatment was undertaken. In February 1942 partial gastric resection of the posterior Polya type was performed for a chronic duodenal ulcer. Between a half and two thirds of the stomach was removed. Subsequent analysis of the gastric contents three weeks after the operation did not reveal any free hydrochloric acid in the stomach even after the injection of histamine. The patient was completely relieved of his symptoms and at the time of dismissal, one month after the operation, was able to eat well.

The operation of gastric resection was chosen not only because it affords the opportunity to remove the ulcer but also because it offers the greatest permanent reduction of gastric acidity. In a previous study one of us⁶ showed that when half of the stomach or more, including the pylorus and antrum, is removed a permanent reduction of the free hydrochloric acid in the fasting contents is obtained and that this reduction is to zero in 75 per cent of the cases. If more than this amount is removed there is only a slight increase of the frequency of the reduction to zero. The significance of this relative achlorhydria will be discussed later. One more requirement which we believe is essential is the removal of the pylorus at the time of the resection. While this often contributes to the difficulty of the operation, we believe that it is essential for the ultimate prognosis and especially for the reduction of acidity.

The following case indicates the clinical laboratory results after failure to remove the pylorus in spite of extensive resection of the stomach. While the prognosis as to ultimate cure and certainly as to immediate relief is favorable, it surely does not offer the same chance for complete cure that pyloric removal does.

CASE 2—A veteran aged 41 was admitted to the United States Naval Hospital, Philadelphia, in May 1940 suffering from acute perforation of a duodenal ulcer. The perforation was repaired and after several months on medical management the patient was dismissed in September 1940. He was advised to remain on a restricted type of dietary regimen. He was readmitted to the hospital in November 1941 with a diagnosis of recurring active duodenal ulcer. Roentgenologic studies at this time revealed an active nonobstructing duodenal ulcer, and analysis of the gastric contents revealed free hydrochloric acid in the fasting contents up to 80 units. For a time relief was obtained by careful medical management, but the symptoms ultimately became intractable and surgical intervention was advised.

In February 1942 resection of the stomach was performed. There was so much inflammation about the duodenal ulcer,

which was at the superior margin, that an inflammation mass the size of a fist and including the head of the pancreas was formed. This extensive inflammatory process precluded the safe removal of any of the duodenum or even of the pyloric portion of the stomach. In the hope of avoiding gastroenterostomy, with the very likely occurrence of a marginal ulcer, gastric resection somewhat after the type advocated by Finsterer was employed. This included removal of almost four fifths of the stomach, leaving a small portion of the pyloric antrum to ensure a safe closure of the stump. The gastric mucosa was further dissected away in this remaining stump to eliminate any secretory activity. The patient made an uneventful recovery and was completely relieved of his symptoms at the time of his dismissal more than a month later. Analysis of the gastric contents three weeks after operation revealed from 10 to 15 units of free hydrochloric acid in the fasting contents of the stomach, which increased to 60 units following stimulation with 0.5 mg of histamine.

The failure to produce relative achlorhydria is due first to the fact that this patient had a virulent type of perforating ulcer. In the study mentioned previously, it was shown that in only about 50 per cent of cases does relative achlorhydria develop after gastric resection has been performed for duodenal ulcer which has previously perforated. The second reason for failure to produce relative achlorhydria was, we believe, the inability to remove the pylorus in this case.

However, it must be recalled that 25 per cent of patients, following gastric resection for duodenal ulcer in which care is taken to remove the entire pylorus, will fail to show relative achlorhydria. The possibility that in this group lies the greater number of those that have recurring marginal ulcers must be considered. Nevertheless the number of patients that had subsequent marginal ulcers in a series reported by Walters, Lewis and Lemon⁶ is about 2 per cent in 212 cases. But there is evidence that those patients who demonstrate recurrence are those who show poorer results from resection so far as acid reduction is concerned. Furthermore, those patients who subsequently have marginal ulcers after gastroenterostomy and are therefore a selected group are definitely less amenable to resection. Walters and Cleveland⁷ reported that only 76.1 per cent of patients undergoing gastric resection for bleeding marginal ulcer were apparently cured, as against 94.4 per cent undergoing gastric resection for bleeding duodenal ulcer.

That the stomach following resection is capable of secreting acid is to be expected, since a large number of acid glands remain in the fundus. Under the stimulation of histamine practically every stomach which was resected can be demonstrated to contain free hydrochloric acid.

Nineteen patients suffering from primary duodenal ulcers on whom resection was performed were given histamine (0.5 mg). In each of these patients no free hydrochloric acid had been present in the fasting contents of the resected stomach. However, after the administration of histamine, free hydrochloric acid was absent in only 1 instance. This patient had had considerable postoperative retention and it is reasonable to assume that the associated deficiency state plus gastritis was responsible for the achlorhydria. In 3 other patients

tested at ten minute intervals for one hour after the injection of histamine, free hydrochloric acid was found in only one ten minute sample in each patient. In 1 patient forty minutes after the injection of the histamine only 10 units of free hydrochloric acid was found. In another patient 4 units was found twenty minutes after

Chart 1—Peak of acid curves in the contents of the stomach following injections of histamine of patients undergoing gastric resection. These patients had all had previous closure of a perforated duodenal ulcer.

injection of histamine and, in still another, 10 units was found fifty minutes after injection of histamine. These 3 patients, to all intents and purposes, can be considered achlorhydric. Thus, from the material available it may be roughly concluded that 75 per cent of patients undergoing gastric resection will have relative achlorhydria and that of these about 25 per cent will have practically absolute achlorhydria.

Chart 2—Distribution of peaks of acid curves following administration of histamine to 23 patients undergoing primary resection for duodenal ulcer. Fifty units was chosen as a convenient and fairly accurate demarcation between a normal and a hyperactive response.

It has been mentioned that an ulcer which had previously perforated was of a more "virulent" type and that patients with this situation were less prone to have relative achlorhydria. Four patients in whom this condition was encountered were studied following resection.

Three of the patients had relative achlorhydria, 1 did not. The data are therefore not sufficient, but there is some increased response to histamine as is shown in the chart of the histamine curves (chart 1). The 1 patient who demonstrated free hydrochloric acid in the resected stomach showed a particularly strong response to stimulation with histamine.

In a previous study it was shown that removal of more than half of the stomach gave only a slight increase of the frequency of occurrence of relative achlorhydria. Histamine tests show little difference in variation of secretion of free hydrochloric acid in relation to the extent of resection. Of 4 patients in whom no free acid was found in the fasting contents of the stomach, the concentration of free acid rose to more than 50 units in only 1. (The level of 50 units was chosen since, as is shown in chart 2, it formed a convenient level of demarcation between apparently normal and marked response to histamine stimulation.) Each of these patients had had only a minimal resection, that is, about half of the stomach, including the pylorus and antrum.

Chart 3—Histamine gastric acid curves of 8 patients undergoing gastric resection for gastrojejunal ulcer. One patient had free hydrochloric acid in the fasting contents of the stomach.

In 15 patients who had had apparently more extensive resection, the free hydrochloric acid after histamine stimulation rose to more than 50 units, although not to more than 60 units.

RESECTION FOR GASTROJEJUNAL ULCER

Clinically, these cases represent a selected group (since in only a fraction of cases in which gastroenterostomy is performed for duodenal ulcer do gastrojejunal ulcers subsequently develop). Following resection, they yield less satisfactory results than the other cases as far as acid reduction is concerned. Thus, after histamine tests the acid concentration in 3 cases in which there was no free hydrochloric acid in the stomach rose to more than 60 units, and in another it was more than 50 units. Only 1 patient in the group of 8, however, had free hydrochloric acid in the resected stomach. His response to histamine stimulation was somewhat greater than normal with a peak of 58 units of free hydrochloric acid in thirty minutes (chart 3). In all these cases a particular effort was made to perform as high a resection as was compatible without increasing greatly the surgical risk. In spite of the

increased extent of resection these patients did not show any improvement in reduction of acidity, and, in fact, there was a tendency to respond more vigorously to histamine stimulation

SIGNIFICANCE OF PRESENCE OF FREE HYDROCHLORIC ACID IN THE FASTING CONTENTS OF THE STOMACH

By far the most significant factor in the entire study was the presence of a trace of free hydrochloric acid in the fasting contents of the stomach. In these cases the concentration of free hydrochloric acid rose rapidly and reached peaks higher than in any other type of curve (chart 4). The highest concentration was 90 units in a patient who had a concentration of 28 units in the contents of the fasting stomach. Furthermore, in almost all cases the acid concentration was fairly well sustained. This uniform tendency to higher concentration of free hydrochloric acid following stimulation with histamine indicates the importance of obtaining at least relative achlorhydria following gastric resection. The

Chart 4—Effect of the presence of free hydrochloric acid in the fasting contents of the stomach on the response to histamine. Note the uniformly strong concentration of acid.

fact that 25 per cent of patients suffering from duodenal ulcer who undergo gastric resection do not obtain relative achlorhydria indicates that, while gastric resection is an advance in the treatment of duodenal ulcer, it is not always a certain means of eliminating the acid factor. Chart 1 illustrates the histamine stimulated acid concentration in the resected stomach of a patient who had had previous perforation of his ulcer and in whom 8 units of free hydrochloric acid was found in the fasting contents. The strong and persistent concentration of free acid following histamine stimulation is an indication why the prognosis may be less favorable in these cases.

REACTIONS OF THE ACID SECRETORY MECHANISM OF THE RESECTED STOMACH TO HISTAMINE STIMULATION

The response to histamine stimulation is various. (1) No free hydrochloric acid may be demonstrated after administration of histamine in a few cases, (2) the concentration of free hydrochloric acid may rise to a peak and then fall to zero, the so-called single peak

curve (chart 5) or (3) the curve may present two peaks (chart 6). The rise of acidity may cause distress, as in 1 patient in whom the test was discontinued following the development of symptoms similar to his previous ulcer distress. In this instance the acid concentration had risen to 64 units.

Chart 5—Typical single peak type of acid curve.

COMMENT

The various hypotheses about the causation of peptic ulcer have received sufficient comment. The only factor of importance in which surgical management can play a part is the reduction of the acid content of the stomach. The importance of this as an etiologic agent in the production of peptic ulcer has received recent comment in an editorial in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*. Only a small percentage of patients who have peptic ulcer ever receive surgical treatment and often this is because of complications resulting from the ulcer, such as hemorrhage, perforation or obstruction. Gastroenterostomy often will suffice to relieve the symptoms of duodenal ulcer, but it does not carry with it a sufficient reduction of gastric acidity to insure the prevention of recurrence. Gastric resection, including removal of the pylorus with the lower half of the stomach, is the best method of controlling hyperacidity. When symptoms are intractable and the

Chart 6—Double peak type of acid curve.

patient is a young man, it is the best operation, as a rule, available. This is the problem faced in military life and, as has been emphasized recently, this is a serious situation.⁵ The solution of this problem lies probably in the surgical management of these ulcers, since medical control in military life is virtually impossible.

The present study has been devoted to evaluating the actual reduction of gastric acidity by means of properly performed and indicated gastric resection. This operation is the best available to minimize the acid content of the stomach as an etiologic agent in gastric ulcer. Even under the stimulation of histamine a considerable reduction of acidity is evident. That gastric resection is not always entirely successful, however, is also demonstrated. Dangerously high acid levels are still encountered under the influence of histamine stimulation, levels high enough to cause a return of symptoms, as they did in 1 case. The value of obtaining relative achlorhydria has been indicated, since patients who have even a trace of free hydrochloric acid in the resected stomach have acid concentrations uniformly higher than those with relative achlorhydria. Similarly in selected cases, such as those in which there has been previous perforation or in which there is gastrojejunal ulceration, acid concentrations are reduced considerably, but not quite as satisfactorily as in those in which primary resection is being done for duodenal ulcer (a more random selection).

CONCLUSIONS

1 Reduction of gastric acidity is obtained in 75 per cent of cases in which gastric resection is performed for primary duodenal ulcer, which may be considered as affording a good prognosis, since it eliminates the acid factor as an etiologic agent.

2 A trace of free hydrochloric acid in the contents of the stomach following resection indicates a less satisfactory reduction than would seem indicated on the surface, because the response to histamine stimulation is uniformly greater than in those patients obtaining relative achlorhydria.

3 Patients who have an ulcer difficult to control as evidenced by previous perforation or marginal ulceration are also less amenable to surgical treatment than other patients, and gastric resection in such cases should be as thorough as is compatible with surgical risk.

ABSTRACT OF DISCUSSION

DR. WALTER WALTERS, Rochester, Minn. Dr. Shaar called attention to the incidence of ulcers of the stomach and duodenum in the fighting forces of our allies of the British Empire. In a report of 1,000 patients admitted to a hospital in England, 10 per cent of them were admitted as the result of dyspepsia, and of these patients about 50 per cent had ulcers. A significant fact in the study of the English literature was that patients suffering from active ulcers are found to be ineffective soldiers and sailors and are discharged from the service. On the other hand, my understanding is that men who have had partial gastrectomy and who have been free from symptoms are retained in the service. The same plan applies to patients on whom gastroenterostomy has been performed. One must distinguish constantly between the operations performed for gastric ulcers and for duodenal ulcers, because the two lesions are entirely different. As brought out in the paper, resections of the stomach for gastric ulcer are followed in about 100 per cent of the cases by relative achlorhydria. The achlorhydria is relative because stimulation of the gastric secretion by histamine in those cases almost universally shows the presence of hydrochloric acid. On the other hand, when similar types and magnitudes of gastric resection are performed for duodenal ulcer and a Polya type of anastomosis is performed, in only 75 per cent of the cases does relative achlorhydria develop. If patients of a similar type have a section of their stomachs removed and have a Billroth I type of anastomosis, relative achlorhydria develops in only 25 per cent. What is the effect of gastroenterostomy on gastric acid?

It is that in 12 per cent of the cases relative achlorhydria develops, as shown by work carried out by Lieutenant Cleveland some years ago. I would call attention to the difference in technique in the Polya and the Billroth operations because of the importance that the Polya, rather than the Billroth, plays in the treatment of duodenal ulcers in which resection is performed. The same amount of stomach is removed, including the first part of the duodenum in which the ulcer is located, but in the operation of Polya the end of the duodenum is closed and peristalsis carries the duodenal, biliary and pancreatic secretions into the stomach. In 75 per cent of cases in which this operation has been done for duodenal ulcer relative achlorhydria will develop. When the same amount of stomach has been removed in cases of duodenal ulcer and the end of the stomach has been sutured to the end of the duodenum, peristalsis carries the alkaline duodenal, biliary and pancreatic secretions into the second and third portions of the duodenum rather than into the stomach. In only 25 per cent of these cases does relative achlorhydria develop. The incidence of recurring ulcer following the Billroth I operation for duodenal ulcer is 5 per cent. In only 4 per cent of cases in which gastroenterostomy has been performed, in which there is a gastric acid dilution factor because of the reflux of the alkaline intestinal secretions into the stomach, does recurring ulcer develop. In the Polya and Billroth operations for gastric ulcer recurring ulcerations do not take place, and probably one of the reasons is that, in both of those types of operations performed for gastric ulcer, relative achlorhydria usually results.

EVIDENCE ON THE GENESIS OF PEPTIC ULCER IN MAN

STEWART WOLF, MD

Captain M. C. L. S. Army

AND

HAROLD G. WOLFF, MD

NEW YORK

Recent studies have shown that prolonged continuous acceleration of acid secretion in the stomach by the repeated administration of histamine in beeswax results regularly in the development of duodenal ulcer in a wide variety of laboratory and domestic animals.¹ Some what earlier it was shown that in dogs the maintenance of hyperacidity by continuous stimulation of the vagus or by continuous sham feeding² resulted in ulcer.

While all these stimuli seem to cause ulcer by a common mechanism, namely by effecting a continuous hypersecretion of acid in the stomach, not one of the three is ordinarily operative in human beings subject to ulcer. It was with the purpose of discovering some stimulus which results in definite, sustained acceleration of acid production and which may have been recurrent in the ordinary course of life in ulcer patients that our studies were undertaken. We found that day to day life situations which provoked certain patterns of emotional reaction induced hypersecretion in the stomach comparable to that resulting from prolonged absorption of histamine, vagus stimulation and sham feeding.

PREVIOUS WORK

Wittkower⁴ found that while certain subjects reacted to test situational stimuli by decreased gastric function in line with Cannon's hypothesis,⁵ certain others showed accelerated acid production in the stomach. Gordon and Chernya,⁶ who studied acid secretion in several human subjects with gastric fistulas, found that one of their subjects whose tasting secretion had previously been within normal limits began to show hyperacidity when he became homesick, restless and resentful of the experimental procedures. More recently Mittelman and Wolff⁷ published a study of normal subjects and patients with peptic ulcer. During periods of experimentally induced anxiety, hostility and resentment, they found a rise in acidity and increased contractions in the stomachs of all the patients suffering from ulcer and in many of the normal subjects. Moreover, they were able to reverse this process and cause a decrease in acidity and motility by inducing in their patients feelings of contentment and well-being.

Reviewing the life histories of the patients with ulcers, Mittelman and Wolff found that the patients had been subject to prolonged emotional turmoil involving mainly conflict, anxiety, guilt, hostility and resentment. The occurrence of pain and even hemorrhage was correlated with periods of special stress and accentuation of these feelings.

In view of this evidence we undertook studies on a subject whose gastric mucosa could be examined readily for prolonged periods.

METHOD

Our studies have been made on a man aged 56 who at the age of 9 completely occluded his esophagus by drinking scalding hot clam chowder. Since then he has fed himself through a gastric fistula 3.5 cm in diameter, surgically produced shortly after the accident. It is his custom to put food into his mouth and, after tasting and chewing it, to expectorate it into an ordinary kitchen funnel inserted into his stoma. Through the stoma has protruded on his abdominal wall a collar of gastric mucosa essentially similar to that within the cavity of the stomach. The patient is in excellent health, has rare digestive complaints and is employed as a diener in our laboratory. He is a small, wiry man of Irish-American stock, unschooled, married and the father of one child. He is shy, sensitive, proud, stubborn and slightly suspicious. He is fun loving but very conscientious.

We made estimates of vascular changes by comparing changes in color in the gastric mucosa to a standard color scale, which was calibrated after the method of Munsell. That these variations actually reflect changes in blood flow was shown by measurements with a blood flow recording device reported elsewhere.⁸

The stomach was emptied every fifteen minutes and the juice obtained was analyzed in the usual manner. The output of acid by the parietal cells was estimated with reference to volume and acid concentration and was expressed in cubic centimeters of 0.166 normal

hydrochloric acid according to a method of calculation described elsewhere.⁹

In many of the experiments records of the stomach contractions were made by the familiar technique of inflating in the organ a balloon connected to a recording manometer.

Careful note was made of the patient's mood and the content of his thoughts and preoccupations. These data were collected during the experiments as well as at separate daily interviews. An attempt was made to classify the emotional and other reaction patterns as contentment, joy, gratitude, feelings of helplessness, dejection, doubt, fear, frustration, guilt, sadness, anxiety, tension, hostility and resentment. None of these existed alone, but usually it was possible to recognize one or two as dominant. The emotional reactions were then correlated with the various measurements of gastric function.

The emotionally charged situations were not experimentally induced. Spontaneously occurring life situations, problems and conflicts were utilized. Some of these involved events arising from time to time in the laboratory. Others occurred in the setting of the subject's home life. His reaction to each of these experiences

Fig. 1—A phase of accelerated gastric function showing waves of vigorous contraction and the associated blushing of the mucosa. Acid was being produced at the rate of 4 cc. of hydrochloric acid an hour during the quiescent phase before and after. During the period of vigorous contractions acid production was accelerated to 16 cc. an hour.

was evaluated in the light of his individual personality pattern, which is described in detail in another publication.⁹ Thirty-four observations on stomach function accompanying several different affective states were made. From these illustrative examples will be presented.

OBSERVATIONS

Secretion, Motility and Vascularity Under Conditions of Relaxation and Well-Being—During periods when the subject was relaxed and apparently contented, the color of the mucosa remained relatively constant in the neighborhood of 50. Contractions were usually of low amplitude and rhythmic making a pattern of three small waves a minute.

Gastric juice accumulated in the stomach at the rate of approximately 8 to 15 cc. an hour. Total acid under these circumstances averaged 50 clinical units. In terms of parietal cell output, according to our calculation, this represents about 3 to 5 cc. of 0.166 normal hydrochloric acid an hour.

Spontaneous Periodic Phases of Accelerated Gastric Function—Every two to three hours there occurred in the stomach a transitory phase of hyperemia, hypersecretion of acid and vigorous contractions. These followed a rather constant pattern, as shown in figure 1,

and lasted only twenty to thirty minutes. After the phase of accelerated gastric function had subsided the stomach assumed its former "basal" condition. The changes obtained during test situations were carefully evaluated with regard to these periodic phases of spontaneous gastric hyperfunction.

Fig. 2—Pallor of the gastric mucosa and decreased rate of acid secretion accompanying fear.

Correlation of Gastric Function, Acid Production, Motor Activity and Vascularity—Combined measurements of the rate of acid secretion, gastric contractions and vascularity were made under a wide variety of circumstances and after various stimuli. At all times increased acid production was accompanied by hyperemia, and hyperemia always indicated increased acid production. Vigorous contractions, while they did not always accompany hyperemia, did not occur when the stomach was pale.

Depression of Gastric Function in Association with Fear and Sadness—**Fear**—The patient suddenly experienced intense fear one morning in the midst of a phase of accelerated gastric function. An irate doctor entered the room muttering imprecations about an important protocol which had been lost. Our patient had mislaid it and feared that he had lost the record and his job. He lay motionless on the table and his face became pale. Prompt and decided pallor occurred also in his gastric mucosa, and associated with it there occurred a fall in the rate of acid production. A minute later the doctor found his paper and left the room. Forthwith the face and gastric mucosa of our patient regained their former color (fig. 2).

Sadness—Sadness, dejection and feelings of self reproach were accompanied in our subject by taciturnity, lack of "energy," slowness of movement of the body generally and by pallor of the gastric mucosa, decreased acidity and motor activity. Even the stomach's normal response to the ingestion of food was inhibited under these circumstances.

One morning the patient was depressed and uncommunicative over having lost through his own negligence

an option on a house which he had long been eager to acquire. He was limp and dejected and filled with feelings of self depreciation and refused to relate the nature of his trouble until several hours later. We administered beef broth directly into his stomach and noted that the hyperemia and acceleration of acid production and motility, which regularly followed ingestion of beef broth, were partially inhibited. Figure 3 shows normal response to beef broth and figure 4 the response obtained during sadness and dejection.

Acceleration of Gastric Function in Association with Emotional Conflicts Involving Anxiety, Hostility and Resentment—During a period of "basal function" of the stomach one-half hour after a spontaneous phase of accelerated function, a member of the staff entered the room to pay off and discharge our subject from a job he was doing for the doctor after hours in order to earn extra money. The doctor had complained earlier that he was slow, ineffective and charged too much. The subject, who takes great pride in his conscientious attitude toward all duties, resented heartily these charges. When the physician told him he need not report for work any more he accepted the rebuff politely, but quickly his stomach became red and engorged and soon the folds were thick and turgid. Acid production accelerated sharply and vigorous contractions began. This happened despite the fact that another spontaneous phase of accelerated gastric function was not to be expected for at least an hour and a half (fig. 5).

We noted these changes frequently in association with feelings of strong hostility and resentment on the part of the patient, and also with anxiety. It is noteworthy that these incidents occurred far more commonly than did those described earlier, in which there was an associated inhibition of secretion, motor activity and vascularity.

The degree and duration of the changes in gastric function were also roughly proportional to the intensity and duration of the emotional reaction.

Fig. 3—Usual response to ingestion of beef broth.

An illustration of prolonged acceleration of gastric function is as follows. The patient was usually in a state of comparative financial insecurity, and because of this he was compelled to accept gifts from a certain benefactor. The latter meddled in our subject's personal affairs and when denied a hand in managing them threatened to withdraw support. During two weeks

of much meddling our patient became intensely anxious about his future welfare and resentful of the activities of his benefactor. He was eager to throw off his dependence. At the end of the two weeks the opportunity for release came in the form of a raise in pay for his job at the hospital. This good fortune he received with the deepest feelings of relief. Figure 6 shows the average levels of acid production and color of the mucous membrane of his stomach during the two weeks of emotional turmoil and during the two weeks preceding and the two following it.

Gastritis, Pain and Mucosal Erosions—In the presence of hypermotility and hypersecretion, the gastric mucous membrane not only became red but engorged and turgid as well. The folds became thicker and succulent and the lining of the stomach presented the picture designated by gastroscopists as 'hypertrophic gastritis'.

During periods when his stomach was in this state, occurring as they did in association with emotional conflicts involving anxiety, hostility and resentment, the patient often complained of heartburn and abdominal pain. Indeed it was possible to demonstrate experi-

Fig. 4—Inhibition of beef broth effect during sadness and dejection

mentally that the tissues of the stomach wall were more sensitive to pain in their hyperemic state than normally. Vigorous contractions of a magnitude insufficient to cause pain in its normal state were painful when the stomach was intensely engorged.

Furthermore, the susceptibility of the mucosa to injury resulting in hemorrhage was found to be greatly enhanced in this condition of engorgement and hyperemia. Even relatively trifling traumas such as striking the membrane with a glass rod or stroking it with dry gauze resulted in small erosions and bleeding points. Frequently during periods of such hyperemia vigorous contractions produced bleeding points around the periphery of the exposed collar of mucosa without the necessity of instrumentation.

Healing in the Stomach. The Protective Properties of Mucus—Ordinarily these small erosions and bleeding points which occurred from time to time were quickly covered with mucus and healed uneventfully in twenty-four hours or less. The failure of any of these lesions to persist as a chronic ulceration will be shown to be due largely to the effective protection afforded by the mucus.

When irritating substances such as mustard, strong acid or alkali were placed on the lining of the stomach without pains being taken to remove the mucus coating, only a slight to medium erythema resulted. When the

accumulation of protective mucus was continually aspirated away, however, and mustard was applied directly to the cells of the mucosa, acute inflammation and edema resulted. Bleeding points and small erosions appeared throughout the area involved. Pinching and faradic stimuli applied to the mucosa in this condition caused

Fig. 5—Accelerated gastric function accompanying emotional conflict involving feelings of hostility and resentment

pain, although pain did not occur when these stimuli were applied to the mucosa in its normal state.

The protective powers of mucus have been shown to consist of three distinct mechanisms. First, it presented a continuous slippery surface to irritants. Second, by combining with and neutralizing the acid in immediate contact with it, it maintains the acidity of the stomach lining itself at a relatively low level. When a drop of Toepfer's solution was allowed to fall on the wall of the stomach it failed to indicate an acid reaction.

Fig. 6—Prolonged gastric hyperfunction accompanying sustained anxiety for two weeks

despite the fact that a sample from a nearby pool of accumulated gastric juice contained 65 units of titratable free acid. An important aspect of this protective device is the fact that mechanical and chemical irritation of the gastric mucosa as well as the presence of acid in high concentration in the stomach accelerates the rate of production of mucus. Circumstances arose, how-

ever, when the amount of acid in the stomach exceeded the powers of this compensatory mechanism. Then the third protective property of mucus was invoked. The mucus precipitates and forms an insoluble, continuous, tough, membranous coating over the cells of the gastric mucosa, thus insulating them from chemical attack.

In the duodenal cap the protection afforded the cells is far less elaborate, and whatever mucus does cover the cells is likely to be brushed aside by food. Thus the corrosive contents of the stomach can gain access to the base of a minor erosion.

Result of Continued Contact of Gastric Juice with a Mucosal Erosion—To demonstrate the effects of contact of gastric juice with an eroded surface, we conducted the following experiment.

Two small bleeding points were produced in the gastric mucosa by traumatizing it with a smooth-edged forceps. These tiny eroded areas were kept in contact with gastric juice of a titratable total acid of 90 units for one-half hour. The protective mucus which accumulated rapidly in this region was sucked away frequently and fresh gastric juice applied. A sharp acceleration of acid secretion and concomitant hyperemia of the whole gastric mucosa resulted from this procedure, and these effects persisted for one-half hour after the exposure of the erosions to the action of gastric juice had been stopped. After the undisturbed lesions had become covered by mucus the color and acid values returned to normal.

This experiment supports the idea that the acceleration of acid secretion resulting from erosions being bathed in gastric juice is one mechanism involved in the maintenance of hyperacidity in patients suffering from peptic ulcer.

Fig. 7—A, normal mucosal folds (actual size), B, engorgement of mucosa accompanying emotional conflict (actual size), C, mucosal erosion (actual size), D, punched out ulcer resulting from prolonged contact of gastric juice with an area of mucosa inadequately protected by mucus (actual size).

Gastric Juice and Chronic Tissue Damage—On the peripheral border of the collar of mucous membrane which lay exposed on the patient's abdominal wall a situation similar to that encountered in the duodenal cap prevailed. Here, owing to defective production of mucus, there was little or no protective covering over

the mucosa. This state of affairs enabled us to test the consequences of inadequate supply of insulating mucus by the following experiment.

A small erosion which occurred in this region was continuously subjected to the action of the patient's own gastric juice for four days.

Fig. 8—Drawing of ulcer shown in figure 7 D (enlarged five times).

Within twenty-four hours the denuded surface had increased in size. The base of the lesion became deeper and it bled intermittently. At the end of four days it measured 4 mm in diameter and presented the punched out appearance of a chronic peptic ulcer with well defined edges and a granulating base (figs 7 and 8). Traction or pressure applied to the lesion caused pain. While this lesion was present the whole mucosa remained relatively engorged, and acid production was maintained at a high level.

After four days the ulcer and surrounding area were covered by a protective petrolatum dressing and thus isolated from the gastric juice. Complete healing took place within three days, leaving no grossly recognizable trace of the lesion behind.

Thus it has been shown that when an unprotected mucosal erosion is exposed to the digestive action of gastric juice additional tissue damage occurs and chronic ulceration results.

COMMENT

The difference between a hypersecreting stomach and actual gastritis is, as we have shown, mainly one of degree. Prolongation of inordinate hypersecretion in the stomach with the inevitable accompanying hyperemia, then, carries with it the hazard of possible structural damage to the lining of the stomach or even more likely to that of the duodenal cap, since the latter is less well protected.

Once an erosion has been effected, contact of acid gastric juice with the denuded surface would perpetuate the vicious cycle as illustrated in the experiment described.

We have shown that situational factors resulting in emotional conflict with anxiety, hostility and resentment may induce in the stomach profound and prolonged hyperemia, hypermotility and hypersecretion. Adequate neural mechanisms exist to explain these phenomena, and indeed experimental ulcers have been produced in animals by lesions in the brain stem,¹⁰ by prolonged stimulation of the vagus² and by infusion with acetylcho-

line¹¹ The necessity for the gastric hyperfunctioning to be sustained as well as pronounced is apparent in the failure of large repeated doses of histamine in aqueous solution to result in ulcer¹² When a sustained effect was obtained, however, by administering the drug in a slowly absorbed medium, peptic ulcer regularly resulted¹³ The reason why our patient has not acquired peptic ulcer may be that the hyperemia and hypersecretion which we have observed in the presence of conflict have been relatively transitory He is not the sort of person who harbors grudges or maintains emotional stress for prolonged periods Usually he expressed his feelings either in words or in action, and his more serious conflicts were relatively short lived Since the occurrence of gastric hyperfunction in certain emotional settings has been demonstrated however, and since the destructive power of excessive gastric secretion has been established, one may infer that these emotionally charged situations are involved directly in the genesis of peptic ulcer in man Hyperacidity, gastritis, minor mucosal erosions and finally peptic ulcer occurring during the course of sustained emotional tension should not be looked on as separate clinical entities The evidence indicates that they are all phases of the same pathologic process

SUMMARY AND CONCLUSIONS

A patient with a large gastric fistula whose mucosa is readily accessible to view has been studied with regard to the possible genesis and persistence of tissue damage It was found that

1 Acid in small amounts was continuously elaborated in the subject under basal conditions

2 Spontaneous transitory phases of accelerated secretion of acid occurred from time to time These were accompanied by blushing of the mucous membrane and vigorous contractions of the stomach wall

3 Emotions such as fear and sadness, which involved a feeling of withdrawal, were accompanied by pallor of the gastric mucosa and by inhibition of acid secretion and contractions This complex was encountered infrequently in our subject

4 Emotional conflict involving anxiety, hostility and resentment was accompanied by accelerated acid secretion, hypermotility, hyperemia and engorgement of the gastric mucosa resembling 'hypertrophic gastritis' This series of events was much more commonly observed in our subject It was associated with gastrointestinal complaints of the nature of heartburn and abdominal pain

5 Intense sustained anxiety, hostility and resentment were found to be accompanied by severe and prolonged engorgement, hypermotility and hypersecretion in the stomach In this state mucosal erosions and hemorrhages were readily induced by even the most trifling traumas, and frequently bleeding points appeared spontaneously as a result of vigorous contractions of the stomach wall

6 Contact of acid gastric juice with such a small eroded surface in the mucous membrane resulted in accelerated secretion of acid and further engorgement

of the whole mucosa Prolonged exposure of such a lesion to acid gastric juice resulted in the formation of a chronic ulcer

7 The lining of the stomach was found to be protected from its secretions by an efficient insulating layer of mucus, enabling most of the small erosions to heal promptly within a few hours Lack of such a protective mechanism in the duodenal cap may explain the higher incidence of chronic ulceration in this region

8 It appears likely, then, that the chain of events which begins with anxiety and conflict and their associated overactivity of the stomach and ends with hemorrhage or perforation is that which is involved in the natural history of peptic ulcer in human beings

PULMONARY TUBERCULOSIS MASQUERADING AS LARYNGITIS

JOSEPH C DONNELLY M D

PHILADELPHIA

My purpose in this paper is to call attention to or promote wider recognition of the fact that pulmonary tuberculosis may first be manifested by laryngeal symptoms It is not to be construed that the tuberculous process originates in the larynx, because it is axiomatic today that laryngeal tuberculosis is always secondary to a pulmonary focus Unlike hemoptysis, which is so alarming to the patient and significant to the physician, the presence of either chronic hoarseness or sore throat is frequently disregarded as a serious warning by both patient and consultant

While the incidence of laryngeal symptoms antedating pulmonary or systemic signs is small, nevertheless a review of the history and laryngeal examination of 1,800 patients observed at the White Haven Sanatorium revealed that the cart came before the horse in 26 of these patients, or a frequency approximating 1.5 per cent It would have been instructive to know the interval of time that elapsed between the onset of the laryngeal symptoms and the discovery of the pulmonary lesion, but circumstances prevented the obtaining of this information The data however, were available in several instances, and it is my impression that three or four months elapsed in the average case before adequate diagnostic measures were instituted It is not maintained in this report that the patients' symptoms were exclusively laryngeal, because occasionally the discerning practitioner uncovered latent pulmonary and systemic signs It is held, however, that in the great majority of cases the initial symptom of hoarseness or sore throat so predominated the clinical picture that priceless time was lost either in observation or in local therapy before the pulmonary lesion was discovered

SYMPTOMS AND DIAGNOSIS

The insidious onset of pulmonary tuberculosis is well illustrated in this selected group of patients whose apparent well-being was the chief misleading factor in the diagnosis Of the 26 patients with laryngeal tuberculosis at the time of admission to the sanatorium 16 had hoarseness, 4 complained of a sore throat while the remaining 6 had both symptoms I cannot state

13 Varco R L, Code C F, Walpole S H and Wangenstein O H Duodenal Ulcer Formation in the Dog by Intramuscular Injections of a Histamine Beeswax Mixture Am J Physiol 133 P475 (June) 1941

From the Department of Laryngology of the White Haven Sanatorium, White Haven, Pa.
Read before the Section on Laryngology, Otolaryngology and Rhinology at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 19, 1942

with certainty that at the onset of their illness the lesions were tuberculous, but in view of the subsequent events, the increased severity of symptoms, it is quite reasonable to assume that the laryngeal involvement was specific from the beginning. The average duration of the laryngeal symptoms or the time that elapsed between the onset of illness and admission to the sanatorium was six months. The following studies,

TABLE 1—Age and Sex of Patients

Age	Male	Female	Total
15-20	0	1	1
21-30	6	5	11
31-40	2	3	5
41-50	5	0	5
51-60	2	0	2
60-75	2	0	2
Total	17	9	26

therefore, must be viewed in the light of this interval. According to the Standards of the National Tuberculosis Association, the severity of the symptoms of these 26 patients may be grouped as follows. The condition of 11 was severe, of 8 moderate and of 7 slight. The sputum of 21 was positive and of 5 negative. The sedimentation rate was determined in 18 of the patients and ranged from 13 mm to 35 mm, with an average of 23 mm. These patients were observed during a seven year period, and at the present time 19, or approximately 73 per cent, have died and 7, or 27 per cent, have been classified as apparently cured. In the latter group it is found that only 1 patient had a severe grade of toxicity manifested by a rapid pulse and a temperature elevation of over 2 degrees F. Two of the 7 patients exhibited a moderate toxemia with a fever of less than 2 degrees F, while the remaining 4 had only slight constitutional symptoms with a slight cough and fatigue and a temperature elevation of less than 0.5 degree F. Of the 5 patients with negative sputum 4 were in this apparently cured group of 7 patients. In other words, the sputum was positive in only 3, or 42.8 per cent, while in the fatal group of 19 the sputum was positive in 18, or 94.7 per cent.

I thought that a further consideration of the length of illness prior to sanatorium regimen and collapse therapy might be of value if the 19 cases of fatal involvement were compared with the 7 in which there was an apparent cure, but again I found that the average length of incapacity was six months in each group. However, it should be pointed out that the group of 7 apparently cured patients included a middle aged man with a tuberculoma of the left ventricle who had been ill for eighteen months before admission to the sanatorium. If one were to exclude this long-standing case in our estimate of the ill period one would find that adequate treatment was begun in 6 out of the 7 cases of apparent cure two months earlier than in the 19 fatal cases. It appears therefore that if the symptoms of laryngitis which occasionally herald the onset of pulmonary tuberculosis were recognized sooner and followed by modern therapy the prognosis would be favorably influenced.

Unfortunately in this group of cases the diagnosis was not made until the telltale pulmonary and systemic symptoms developed. Generally it was the advent of cough, fatigue, loss of weight and fever that awakened in the mind of the practitioner the possibility of pulmonary tuberculosis. With the discovery of the pulmonary focus by means of either roentgen, fluoro-

scopic or sputum examination it was presumptively concluded that the laryngeal disorder was also tuberculous. Subsequent events proved in all instances that the practitioner was correct in predicating the laryngeal disease as a complication of the pulmonary focus. Since laryngeal tuberculosis is so rarely encountered in general practice, it hardly seems warranted in this report to dwell on the diagnostic points by which the lesion might have been diagnosed through mirror examination. Suffice it to say at this time that when the least doubt is present the finding of a definite chronic lesion anywhere in the larynx should immediately call for roentgen studies of the lungs and sputum examination to rule out pulmonary tuberculosis.

The age and sex of the patients summarized in table 1 show approximately twice as many men (17) as women (9) whose initial symptom of pulmonary tuberculosis was referred to the larynx. The preponderance of the male sex in this series is all the more noteworthy since in our institution the usual laryngeal complication is only 7 per cent greater among men than among women. The large number (11) in the third decade was to be expected, since pulmonary tuberculosis is most prevalent during this period. The youngest patient in the group was a girl aged 16 while the oldest was a man aged 73. The average age of the males was 40 and of the females 27. Particular attention should be drawn to the 9 cases in men past middle life, since the diagnosis of tuberculous laryngitis had necessarily to exclude a malignant condition and syphilis. The summary shows therefore 26 patients out of 1,800 whose insidious onset of pulmonary tuberculosis was ushered in by either hoarseness or sore throat. The incidence of approximately 1.5 per cent is high when compared to the report of Stevenson and Heaf,¹ who found only 18 similar cases in their investigation of 2,831 patients. In 1,000 cases of laryngeal tuberculosis reported by Myerson,² 25 presented laryngeal symptoms as the first sign of disease.

An appreciation of the pulmonary status of the patient is essential in the proper management of laryngeal tuberculosis. In table 2 are summarized the roentgen findings of Drs. John T. Farrell and E. Robert Wiese of the White Haven Sanatorium staff showing

the extent and type of pulmonary lesions grouped according to the Standards of the National Tuberculosis Association. Of the 26 cases 12 were moderately advanced and 14 were far advanced. The absence of any minimal lesion was rather surprising in view of the fact that the pulmonary tuberculosis in 3 instances was discovered five, six and seven weeks respectively after the initial onset of laryngitis. It is evident from

1 Stevenson R. S. and Heaf F. R. G. Tuberculous Laryngitis. An Analysis of Four Hundred and Twenty Eight Cases. Brit. M. J. 1 164 169 (Feb. 3) 1940.

this small series that while hoarseness or sore throat may first herald the advent of pulmonary tuberculosis it is by no means an early sign

Based on the pathogenesis of the pulmonary lesion the terms exudative and productive are used to describe the two main types into which tuberculosis is roughly divided According to Ornstein and Ulmar,³ the exudative reactions are characterized by a high tissue sensitivity to the tuberculous antigen, so that there is an immediate explosive reaction whenever the tissue of the host comes in contact with the tubercle bacilli The response is chiefly serous, with but little fibrin and a small amount of cellular element On the other hand, when the tissue sensitivity is low and the dose of tubercle bacilli is small the response is productive rather than exudative The reaction is cellular and there is a typical tubercle formation with epithelioid, giant cell and fibroid changes When speaking of an exudative or productive lesion, it is generally implied that the lesion is predominantly exudative or predominantly productive If one reclassifies the two mixed types of lesions shown in table 2 into productive and

The finding of 9 cases of exudative type deserves special mention, since a review of the literature does not show this type of pulmonary lesion associated with primary laryngeal manifestations A typical example of an exudative type of tuberculosis masquerading as laryngitis was found in a woman aged 21 years who in the spring of 1940 consulted her physician because of hoarseness Internal medication was prescribed A month or two later another physician diagnosed her condition as chronic laryngitis Unimproved after a few more weeks, she sought advice from a third consultant, who likewise prescribed internal medication combined with local therapy This plan of treatment was continued through the summer months until the early part of September, when hemoptysis developed The roentgen examination at this time revealed a far advanced unilateral exudative type of lesion, as shown in *B* The mirror examination of the larynx showed an infiltration of both cords in the region of the vocal process This patient responded well to collapse therapy, gaining 24 pounds (11 Kg), and is now in the apparently cured group A subsequent history from

A productive tuberculosis of both upper lobes *B* exudative tuberculosis of left lung *C* miliary tuberculosis of both lungs

exudative, there are a total of 16, or 61.5 per cent, productive lesions and 9, or 34.5 per cent, of the exudative type The preponderance of the productive type was not unexpected in view of the observations of Ornstein and his associates,⁴ who in referring to the productive type of lesion state that because of its avascularity it is apt to give relatively few symptoms, and they further add that the patient may present himself only because of some emphysema or laryngeal or intestinal involvement This occurred when a man aged 47 in our series sought the advice of his physician because of hoarseness and sore throat After a relatively short illness of seven weeks the diagnosis of far advanced tuberculosis was made The lesion of the producing type is demonstrated in the illustration (*A*) The mirror examination of the larynx showed an infiltration of both vocal cords and edema of the epiglottis His death followed five months after onset of his initial symptoms As will be shown later, the extrinsic laryngeal involvement in this case augured a grave prognosis

the patient revealed the presence of a cough from the early onset of her illness, but like others in the series this symptom was masked by the predominant laryngeal complaints

It will be noted in table 2 that only 1 patient had miliary tuberculosis This seemed rather surprising because one would infer from the literature that a primary laryngeal symptom was almost exclusively a manifestation of a miliary type of disease Of 55 cases of hematogenous tuberculosis reported by Cohen⁵ 23 presented the initial symptom referred to the larynx The one patient in our group, a man aged 62, sought the advice of his physician because of a sore throat After a period of three months of local therapy a far advanced miliary lesion as shown at *C* in the illustration was discovered The laryngeal examination revealed extensive ulceration of the epiglottis, both arytenoid areas and aryepiglottic folds The patient died two months after the diagnosis of his pulmonary lesion was made, or five months after his initial symptom of sore throat

Table 3 is an analysis of the lesions from the point of view of the major divisions of the larynx The

intrinsic lesions comprise the vocal cords, ventricular bands and interarytenoid space. The extrinsic include the arytenoid areas, the aryepiglottic folds and the epiglottis. For purposes of a simpler classification, several patients showing a combination of lesions were arbitrarily placed in one group or the other, depending on the location of the predominant lesion. Of the 26 patients 15 had intrinsic lesions and 11 had extrinsic lesions. In the exudative group there were twice as many intrinsic lesions (6) as extrinsic (3), while in the productive group the location of the laryngeal lesions was about equally divided. In the fatal group there was a slight increase of extrinsic lesions (11) over the intrinsic (8), while in the apparently cured group the lesions were all confined to the interior of the larynx. Of the 9 original patients with exudative lesions 5 are apparently cured and have healed larynges, while of the 16 patients with productive lesions only

of 26 cases shows that the laryngeal symptoms were the initial manifestation of pulmonary disease.

2 The chief misleading factor in the diagnosis is the apparent well being of the patients, whose latent pulmonary and systemic signs were masked by laryngeal symptoms.

3 Unfortunately, it appears that laryngitis is not a sign of early tuberculosis, since several of my cases showed moderately and far advanced pulmonary lesions five, six and seven weeks after the initial onset of laryngeal symptoms.

4 In cases of pulmonary tuberculosis complicated by laryngeal involvement the clinician may find guidance in his treatment and prognosis if he is familiar with the location and type of the laryngeal lesion.

2008 Walnut Street

ABSTRACT OF DISCUSSION

DR. FREDERICK T. HILL, Waterville, Maine. Dr. Donnelly's paper is timely because of the present tendency to overlook the laryngeal manifestations of tuberculosis. This is probably due to the decreased incidence of laryngeal manifestations of tuberculosis as a result of the effect of collapse therapy and more intensive methods of treatment. But what should not be condoned is the fact that it is looked for less often and less expertly. For some twenty odd years, I have been doing the consultative work at a state tuberculosis institution. In the early days every patient had a careful laryngeal examination. In the past few years that has not been asked for. On the contrary, the work has been bronchoscopic in efforts to find the source of a persistently positive sputum in cases in which various forms of collapse therapy have been employed. Now we know that the larynx may often furnish the clue to a diagnosis of tuberculosis which otherwise would be missed. I could cite experience with a number of private patients, similar to Dr. Donnelly's. A healthy man of about 60 was referred to me because of persistent sore throat of four months duration. Examination showed an ulcerative area to the aryepiglottic fold which might well be either tuberculosis or cancer. X-ray examination of his chest showed a well defined tuberculous process and biopsy confirmed the diagnosis. I could repeat this experience many times. We must remember that tuberculosis is an insidious disease and oftentimes the larynx may show us the importance of chest x-ray examination. It is unfortunate that so many of these laryngeal cases are seen late, when ulceration or edema exists because of the poor prognosis. I agree with Dr. Donnelly that the productive type is a much more insidious and more difficult one to handle. The most important statement in the paper is the suggestion of the need of more careful routine laryngeal examination, something that is too often neglected. Every larynx should be carefully examined with use of a local anesthetic for a gagging patient.

DR. JOSEPH I. KEMLER, Baltimore. It has been conceded that primary tuberculosis of the larynx is practically nonexistent yet Osler stated that there are cases in which the lesion begins in the larynx or precedes the pulmonary lesion. I had a case many years ago with quite an infiltration of the larynx but with negative findings in the chest. I took out the infiltration on account of hoarseness, because I thought it was not tuberculous. On examination it was found to be a tuberculoma. The lesion had recurred. It was cauterized, and the patient got well. Ten years later the man had hemorrhages and cavitation and died of his tuberculous disease. A nurse was having a low grade fever daily. She was going downhill without any cause being found. Laryngeal examination revealed an infiltration on both cords, typical of tuberculosis. The sputum was at all times negative. The larynx was cauterized until the lesion cleared up, and the girl made an uneventful recovery. There was never enough infiltration to obtain biopsy. Therefore one could not tell exactly the nature of the lesion. But the treatment and the course ran true to form of tuberculosis of the larynx, in spite of the fact that her lungs were absolutely clear.

2 are found in the apparently cured group. In other words, of the 7 apparently cured patients 7 had intrinsic lesions and 5 had an exudative type of pulmonary disease. These figures corroborate the belief that the prognosis is definitely better when only the interior of the larynx is involved, and as far as our investigations show in this selected group of cases the exudative type of pulmonary involvement is the more amenable to cure.

A brief summary of the pathologic findings in the larynx is presented in table 4 showing the usual predominance of infiltrative lesions. In this group, as in any other, the presence of ulceration or edema is frequently a sign of ill omen, while the finding of a tuberculoma—a local manifestation of fibrosis—is usually significant of a favorable prognosis.

SUMMARY AND CONCLUSIONS

1 Pulmonary tuberculosis should always be in the mind of the physician when a patient complains of chronic hoarseness or sore throat. A critical analysis

DR JOSEPH C DONNELLY, Philadelphia Time does not permit a discussion of the contention that tuberculosis may occur primarily in the larynx. Suffice it to say that most authorities agree that the laryngeal involvement is always secondary. The primary focus can be revealed only by the finer diagnostic methods, which were unavailable in the time of Osler. Dr Hill emphasized the need of a more careful routine laryngeal examination of all our patients. This is particularly true for those complaining of a sore throat. Before contemplating tonsillectomy a thorough examination of the larynx should be made.

CONSERVATIVE TREATMENT OF INVERSION OF THE UTERUS

CHARLES E McLENNAN, M.D.

AND

JOHN L McKELVEY, M.D.

MINNEAPOLIS

It has often been said that inversion of the uterus is an extremely rare obstetric complication. However, it is difficult to estimate accurately the true incidence of inversion because of the discrepancy between figures from the older literature and those of recent years. Most early reports cite an incidence of one inversion to several hundred thousand deliveries,¹ while more recently the reported incidence in various clinics has ranged from a high of 1/740 to a low of 1/16,000. Apparently, then, inversion of the uterus occurs with sufficient frequency to make it likely that any one doing obstetric practice will encounter an occasional case. But, as with other rare disorders, accepted standard methods of treatment have not been generally agreed on. This leads to the use of a variety of therapeutic measures of doubtful value and tends to keep the mortality rates at unnecessarily high levels. A glance at the unfavorable mortality rates for inversion (10 to 43 per cent) reported in recent years³ suggests that certain changes in the therapeutic procedures commonly employed might be beneficial.

It is our purpose to point out that the treatment advised in current obstetric textbooks, and indeed in most of the periodical literature, is not necessarily the treatment of choice. Apparently the work on which present conclusions are drawn is almost entirely from the older literature, whereas more recently the approach to the problem has been entirely changed by such factors as (1) recognition of the part that shock plays in the primary mortality from inversion, (2) the effects of immediately available blood for transfusion, (3) methods for the control of infection and (4) improved technics for vaginal surgery. Strangely enough, the obstetricians and the gynecologists have approached inversion from two different points of view, that is, the acute as against the chronic form of the disorder, and have not thought of the desirability of combining their experiences. Results in the chronic form by and large have been satisfactory, whereas quite the opposite is true of the acute variety of inversion following delivery.

To be more specific, Williams⁴ (Stander's revision), De Lee,⁵ Beck,⁶ Titus⁷ and Irving,⁸ as well as others,⁹ are unanimous in recommending immediate replacement of the inverted uterus and the use of deep surgical anesthesia for this purpose if necessary. While it is true that most of these writers have mentioned the necessity of combating shock as a preliminary or simultaneous measure, certainly the emphasis has been on the maneuvers by which the uterus may be replaced. And the desirability of replacing the uterus at the earliest possible opportunity—that is, as soon as the patient shows evidence of rallying from the initial shock—has been stressed repeatedly.

On the other hand, at least two others, Barrows¹⁰ and particularly Brett,¹¹ have already pointed out that immediate replacement of the inverted uterus is a dangerous and unnecessary procedure, that active shock therapy is all important, and that the inversion per se may be dealt with at any suitable time after the patient is restored to normal health and after the lower genital tract has been adequately prepared for surgery—preferably a number of weeks (four to twelve have been advised) after the acute episode. Our recent experiences again have demonstrated the soundness of these principles in the management of inversion. Since this conservative approach to the problem apparently has not met with acceptance, it seems worth while to restate the details of such a therapeutic program and to demonstrate the type of result which may be obtained with it.

Conservative treatment of inversion embodies the following general and specific measures:

1. No procedure which will tend to increase the shock should be employed at the time of occurrence or discovery of acute inversion. Deep surgical anesthesia and forceful attempts at replacement are contraindicated. Vasoconstrictor agents, such as epinephrine, are likely to do more harm than good, since arteriolar tone already is high in the shocked individual.

2. Immediate attention should be focused on the general reaction of the patient. Shock must be anticipated even if not already evident.

3. The inverted uterus may be left entirely alone, unless the extent of the bleeding from it is such as to require the application of a tight vaginal pack or other procedure for the immediate control of hemorrhage. Whatever is done in this regard must not be such as to add to the shock.

4. For the patient who is clearly not in shock and for whom blood has been made available, it may be permissible to undertake a single minor attempt at manual replacement of the uterus, but by and large the attention will have to be directed elsewhere.

5. Multiple blood transfusions (in terms of 500 cc units) are required to combat shock in the average case, particularly if the inversion has gone unrecognized.

until such time as a combination of shock and hemorrhage has brought the patient to a precarious state. When blood is not immediately available, plasma or serum are excellent temporary substitutes and ought to be made available in all institutions handling obstetric cases. After recovery from shock, further blood transfusions may be required to hasten the restoration of normal hemoglobin levels. Particular care must be taken, of course, to avoid isoimmunization reactions associated with the blood factor Rh¹².

6 The placenta probably should be left in situ, if possible, for twenty-four to forty-eight hours in the interest of lessened hemorrhage, although there is evidence in the literature¹³ to suggest that the removal or retention of the placenta is a matter of no particular consequence. Often, of course, the placenta has already been delivered when the inversion occurs or when it is recognized.

7 Systemic chemotherapy with sulfonamide compounds (sulfathiazole, sulfadiazine) should be instituted at once as prophylaxis against both local and generalized infection.

8 Local infection may be reduced to a minimum by repeated (daily) application of antiseptic vaginal packing. For this purpose gauze rolls saturated with an emulsion of acriflavine are recommended, although other similar agents seem to be equally effective¹⁰ and at the same time presumably nonirritating to the uterine or vaginal mucosa.

9 After four to six weeks of observation in the hospital and continuance of the protective measures (chemotherapy and vaginal antiseptics) the now well involuted uterus may be restored surgically to its normal position or may be removed. Plastic procedures directed at replacement and functional restoration of the organ may be undertaken by either the abdominal or the vaginal route. The exact time may be controlled by endometrial biopsy or by the disappearance of gross evidence of infection and evidence of satisfactory involution. When the patient's child bearing is complete or when sterilization is desirable for other reasons, the procedure of choice is vaginal hysterectomy under local anesthesia.

10 There is evidence that an occasional inverted uterus, during the period of preparation for surgical replacement or removal, will undergo spontaneous reinversion¹⁴ and no operative procedure then will be necessary.

To illustrate the efficacy of conservative management, the following 3 cases treated recently in the gynecology service of the University of Minnesota Hospitals are cited.

REPORT OF CASES

CASE 1—A primipara aged 31 was delivered elsewhere by low forceps extraction over a midlateral episiotomy of a normal infant weighing 3,810 Gm after a labor of twelve hours. During the repair of the episiotomy the placenta was removed by a combination of vigorous pressure on the uterine fundus as well as considerable traction on the cord in order to control excessive bleeding. The vagina was packed loosely with a small quantity of gauze and the perineal repair was completed. Shortly thereafter the patient was observed to be in shock, and this was dealt with over a period of six hours by the use of epinephrine, intravenous fluids and blood transfusions. Three subsequent blood transfusions were given over the next several days. Despite lack of healing of the episiotomy

wound the patient was able to leave the hospital on the eleventh postpartum day. At that time a tentative diagnosis of right broad ligament hemorrhage was made to explain the postpartum shock. This was suggested by rigidity and fullness in the right lower quadrant of the abdomen, and it was noted also that the uterus was not palpable abdominally during the immediate puerperium. Two weeks later a secondary closure of the episiotomy was attempted as an office procedure, but this was unsuccessful. At a second office visit, one month post partum, an inversion of the uterus was discovered but no therapy was undertaken at once. During the next two weeks considerable uterine bleeding occurred, sufficient to require hospitalization for blood transfusion, at that time an attempt was made to replace the uterus manually under anesthesia. This was unsuccessful, but the opportunity was taken to attempt again to repair the episiotomy area. Immediately after this procedure the patient again went into shock, which was treated with multiple blood transfusions and artificial respiration. On recovery from this episode she was referred to the University of Minnesota Hospitals for consideration of surgical correction of the inversion. She was now nearly eleven weeks post partum.

Pelvic examination disclosed a dome shaped mass about 5 cm in diameter in the upper vagina, protruding through a partially dilated cervix. The mass was smooth, glistening and bright red and did not bleed on mild trauma. No uterine corpus was palpable above the vagina, the lateral pelvic areas were normal to palpation. The perineum had healed fairly well by second intention. Bacteriologic culture of material from the endometrial surface of the inverted uterus revealed a coagulase positive staphylococcus, gamma streptococcus and *Escherichia coli*. The vagina was treated by daily insertions of gauze packing soaked in acriflavine emulsion, and sulfathiazole was given orally both preoperatively and postoperatively. An endometrial biopsy showed a nonfunctioning endometrium with vascular congestion in the stroma and little or no evidence of inflammation. On June 17, 1941, twelve weeks post partum, the inversion was corrected by the intra abdominal route, with anterior incision of the cervix and lower uterine segment. A small area of stromal and muscular necrosis at the apex of the fundus was excised. The postoperative course was uneventful and the patient left the hospital thirteen days after operation. She was instructed to return in two months for endometrial biopsy and uterine salpingography but failed to do so. Her home physician reports that menstruation recurred one month after the uterine plastic operation and has been fairly regular for eleven months; the flow lasts only three instead of the usual four to five days and is scanty.

CASE 2—An octipara aged 37 induced an abortion on herself by means of a catheter early in the fourth month of her twelfth pregnancy. After somewhat more than two days of excessive bleeding a physician was called to see the patient at home. While he was expressing the retained placenta by suprapubic pressure an inversion of the uterus occurred. The patient was transferred by ambulance to the University of Minnesota Hospitals, a distance of 90 miles, where she arrived three hours after delivery. On admission she was comatose and moribund. Gasping respirations occurred at the rate of four to five per minute, blood pressure and radial pulse were unobtainable, cardiac sounds were barely audible and the heart rate was about 140 per minute. Immediate therapy for shock was instituted. With the patient in steep Trendelenburg posture intra venous isotonic solution of sodium chloride was started, plasma was quickly added and blood was given as soon as cross matching tests had been read. After 200 cc of plasma, 1,500 cc. of blood and 1,000 cc of isotonic solution of sodium chloride had been administered, her blood pressure was 90 systolic and 60 diastolic mm of mercury and she had regained consciousness. Physical examination revealed nothing of consequence other than the inverted uterus within the vagina. The latter was packed with gauze saturated with acriflavine emulsion and the packing subsequently was changed daily. In addition, over a period of three weeks, sulfadiazine was given by mouth, blood levels of sulfadiazine, determined daily, ranged from 8 to 15 mg per hundred cubic centimeters. Initial cultures from the uterus showed a coagulase positive staphylococcus, gamma streptococcus and *E. coli*, but two weeks later

14 Brett H. Barrows¹⁰

only a coagulase negative staphylococcus was found and the uterus was well involuted and clean. Several further blood transfusions were given and the hemoglobin rose from 5 Gm (sample taken at end of initial shock therapy) to 12.25 Gm per hundred cubic centimeters. On the twenty-second hospital day a vaginal hysterectomy, as well as repair of cystocele, rectocele and pelvic floor, was done. Microscopic examination of several areas from the wall of the removed uterus showed a very thin but complete surface epithelium, a few basal glands, hemorrhagic areas and round cell infiltration throughout the stroma, pronounced increase in fibrous constituents of the stroma, and some round cell infiltration in the myometrium. The immediate postoperative course was uneventful and the patient left the hospital on the eighteenth postoperative day. She returned two months later with a complaint of pain in the left pelvis and left thigh, which presumably was attributable to intrapelvic thrombophlebitis. This was relieved by anesthesia of the lumbar sympathetic ganglions and at the present time she is well and free from symptoms.

CASE 3—A secundipara aged 26 was admitted elsewhere in early labor three days after the expected date of confinement for her third pregnancy. After eleven hours of ineffectual uterine contractions a half minim of solution of posterior pituitary was administered intramuscularly. An hour later a premature infant weighing 2,333 Gm was delivered spontaneously from the left occipitoanterior position over a midlateral episiotomy. Repair of the episiotomy was done under nitrous oxide anesthesia. During this procedure 1 cc of solution of posterior pituitary was given to control alarming uterine bleeding and five minutes later the placenta was delivered by strong fundal pressure. Intramuscular ergonovine was given after the third stage of labor, and the uterus was massaged to firmness. Considerable uterine bleeding persisted, despite repetition of the ergonovine. One and one half hours later the patient was in shock—cold, moist, pulse almost imperceptible, air hunger, and blood pressure unobtainable. During the next hour she rallied somewhat under the influence of respiratory stimulants, intravenous dextrose in saline solution and intravenous ergonovine. After a blood transfusion was under way a sterile vaginal examination was performed by a consultant, who had noted absence of the fundus in the lower abdomen, and inversion of the uterus was discovered. The vagina was tightly packed with gauze and an additional thousand cubic centimeters of blood was given. A regimen of daily antiseptic vaginal packing, additional blood transfusions and oral sulfadiazine was carried out during the postpartum hospital stay of thirteen days. The temperature rose as high as 104.6 F on the third postpartum day, subsided slowly and was essentially normal after the seventh day. The hemoglobin rose from 3.6 Gm on the first postpartum day to 10 Gm at the time of discharge.

Although the patient was instructed to present herself at once at the Gynecology Clinic of the University of Minnesota Hospitals, she failed to do so and was not admitted until nine weeks after the delivery. She came at that time because of a pronounced increase in vaginal bleeding, which had been intermittent since delivery. The hemoglobin had dropped to 6.0 Gm. Endometrial biopsy showed a low degree of endometritis in a nonfunctioning endometrium, and culture of material from the endometrial surface showed *Streptococcus viridans*. The vagina and uterus were treated with gauze packs soaked in an acriflavine emulsion, but the trauma associated with this procedure seemed to aggravate the bleeding, so that eventually only the emulsion was used as an instillation. Bleeding from the inverted endometrial surface continued for several days, the hemoglobin dropping as low as 4.45 Gm on the third hospital day. After seven blood transfusions given over a period of five days the hemoglobin was 8.0 Gm, uterine bleeding was minimal and it was decided to carry out vaginal hysterectomy before further serious hemorrhage ensued. This was done under local anesthesia on the eighth hospital day. The postoperative course was uneventful and the patient left the hospital two weeks after the operation. Two months later examination showed an excellent surgical result. Microscopic section of the wall of the uterus showed the endometrial surface epithelium to be missing in many places; a few glands showed no proliferative activity. There was considerable hemorrhage

in the superficial portion of the stroma, an unusually cellular stroma with swollen cells, congestion of small vessels, and a mild lymphocytic infiltration. The myometrium appeared normal.

Contrast with these 3 cases the following 1, with fatal outcome, which was brought to our attention recently during the course of a study of maternal mortality in Minnesota.

CASE 4—A primigravida aged 22 had an uneventful pregnancy and went into spontaneous labor four days prior to her expected date of confinement. After one-half hour in the second stage of labor she was prepared for delivery, midlateral episiotomy was performed, and low forceps extraction of a normal term size infant was done easily under drip ether anesthesia. The episiotomy was repaired in the usual manner and no abnormal bleeding occurred during this procedure. At the completion of the repair the uterine fundus could not be located by abdominal palpation, but the significance of this was not immediately appreciated. The placenta at this time was said to have been just within the introitus and was very easily lifted out by gentle traction on the cord. Abdominal palpation again failed to reveal the presence of the fundus and considerable bleeding appeared at the introitus. Separation of the labia then demonstrated the presence of an inverted uterus. The physician at once attempted to replace the uterus manually. This maneuver, which was unsuccessful, was persisted in for approximately fifteen minutes, during which time the patient lost an estimated liter of blood and went into severe shock. Intravenous 5 per cent dextrose in isotonic solution of sodium chloride was started and 1,000 cc administered. Accurate blood pressure and pulse rate determinations were not recorded, but the pulse was described as being "very weak." Two hours post partum the patient was returned to her room and further supportive therapy consisting of the Trendelenburg position, heat and intravenous fluids (2,000 cc of dextrose in saline solution and finally 250 cc of plasma) was carried out. No transfusions of whole blood were given, apparently because no facilities for blood grouping or cross matching were available in the institution concerned. The patient did not recover from the shock, and death occurred about three hours post partum. Permission for autopsy was not requested. However, the birth canal was examined post mortem and no abnormalities other than the inverted uterus were found.

COMMENT

It is obvious that the management of the 3 patients who recovered was not in all respects ideal. This was due in large part to lack of immediate recognition of the disorder by the attending physicians and lack of a definite program for the treatment of inversion. In case 3, of course, much unnecessary delay in treatment and the added complication of secondary hemorrhage may be attributed to poor cooperation on the part of the patient. Despite these deficiencies in management, the end results were all that could be desired.

In view of these experiences, then, and those of others advocating conservative treatment of inversion, it would seem wise to recommend a reconsideration of the problem of immediate therapy. The high mortality attending this condition may be largely attributed to hemorrhage and shock, and most of the fatalities occur within a few hours after the occurrence of the inversion. Attempts at immediate replacement are well known to increase both shock and hemorrhage. Attempts at replacement later, but in the course of the first few days, either have been largely unsuccessful or have involved surgical manipulations which have unnecessarily increased the danger of spread of infection. We have demonstrated to our own satisfaction that the patient with uterine inversion can at least to a very large extent be protected from the results of shock, hemorrhage and infection. Following recovery, time

may be safely allowed for uterine involution to occur. Correction of the condition may then be carried out at a controlled elective time when the dangers involved appear to be not greater than those of elective gynecologic surgery.

Early recognition of the condition, rapid and efficient treatment of shock and blood loss, avoidance of any uterine manipulation and protection from infection, with postponement of corrective surgery, may be expected to reduce significantly the present serious mortality of inversion of the uterus.

SUMMARY AND CONCLUSIONS

Inversion of the uterus apparently occurs more often than suggested by the usual figures for incidence quoted in obstetric textbooks.

Mortality rates associated with inversion have been and still are excessively high. This would suggest that commonly employed therapeutic measures are in need of revision.

In recent years much improvement in end results has been demonstrated to follow the use of conservative management. This consists of (1) vigorous antishock treatment, (2) disregard for the inverted uterus itself in the acute stage, other than adequate control of bleeding and infection, and (3) surgical correction of the abnormal uterus some weeks later after thorough pre-surgical preparation of the lower genital tract.

Three case histories show the favorable type of result obtained with conservative therapy, with either retention or removal of the uterus, and a fourth case history demonstrates the dangers encountered when the shock associated with inversion is neglected.

ABSTRACT OF DISCUSSION

DR W. BENSON HARER, Philadelphia: I am in complete accord with the idea of Drs. McLennan and McKelvey as to the need for measures to combat shock, hemorrhage and infection. Our difference of opinion hinges entirely on the question of time and methods of replacement of the inverted uterus. For convenience, as to the time of replacement of the uterus, I would divide these cases into three classes: immediate, intermediate and delayed. I have found in 12 cases that immediate replacement readily accomplished the inversion without increasing the shock and with immediate improvement in the general condition of all the patients. By intermediate replacement I refer to attempts at replacement after the cervix has contracted down and while the patient is deep in shock and generally has lost excessive amounts of blood. Here I believe no effort at replacement should be made. By delayed replacement I mean attempts at replacement of the uterus after the patient has recovered from the initial shock. Here again I am in complete accord with the authors. There is no need for hurry. One should take sufficient time to place the patient in the best possible condition to withstand the necessarily extensive surgical procedures required for replacement or removal of the inverted uterus. In 1940 Dr. John Sharkey and I analyzed all the cases of acute inversion of the uterus occurring in Philadelphia in a period of six years. We then had 21 cases. Since that time we have added 4 more cases, making a total of 25. Of these 12 were personally treated. This is still not enough to warrant drawing definite conclusions, but for so rare a condition, the number is sufficient to be suggestive or possibly fairly conclusive. Analysis of the cases presented by Drs. McLennan and McKelvey shows that there was no opportunity to attempt immediate replacement of the inverted uterus. Hence these cases afford no evidence as to the value of immediate replacement. Of the 25 cases 15 were treated by immediate manual replacement of the uterus. All 15 were readily replaced, with immediate pronounced improvement in the general condition. Thirteen of these patients subsequently recovered and 2 died. Five were treated by intermediate manual replacement. All 5

patients died. In these 25 cases, therefore, immediate manual replacement of the inverted uterus gave by far the best results.

DR W. A. COVENTRY, Duluth, Minn.: The rarity of inversion of the uterus makes it evident that such an incident probably will never occur in the practice of the average busy obstetrician, but none the less he should be keenly aware of such an accident. From the remarks of the authors and a review of available literature, there are several lessons to be learned. The endometrial biopsies are of scientific value, tending to show the tendency of the endometrium to assume the character of its new host. The bacteriologic investigations are of less value, since similar types can be found also in the vagina and cervix of noninverted uteri. The practical value of these observations must be recognized. The forceful extraction of the placenta by vigorous down pressure on the fundus of the uterus coupled with undue pulling on the umbilical cord, whether at full term or at any other period of gestation, is not good obstetric practice. This practice is becoming more noticeable among the interns coming to our hospitals. The serious dangers of such a procedure should be stressed by teachers in medical schools. The incident of shock in the third stage of labor is always a reminder of inversion of the uterus. The severity of this incident is undoubtedly due to severe hemorrhage coupled with the disturbed circulation in the inverted uterus. The shock is always severe and requires most vigorous treatment by all the methods stressed in the paper. The manual replacement of the uterus by vaginal or abdominal methods should not be undertaken during the period of shock but reserved until the shock is under control. The precautionary use of the sulfonamide drugs is to be commended. Four to six weeks is too long a period to wait before attempting reposition. Do we wait complete involution of the uterus before replacement is attempted? The lateness of the period in which these cases reported came under the observation of the authors necessitated such operative procedures as noted in their case reports. It would appear to me that the loss of the uterus is too great a penalty to pay in cases of inversion of the uterus and that there should be a safe period after overcoming the shock incident when reposition of the uterus could be done with due respect to the safety of the patient.

DR LOUIS E. PHANEUF, Boston: I have been interested in inversion of the uterus for the last twenty years. The literature during this period has led me to the belief that the incidence reported is too low. Inversion of the uterus is a more common lesion than we are led to believe. The reason for this is obvious as a number of observers who might have had but 1 case have never reported them. The accumulation of these isolated instances would considerably raise the incidence. Another factor which has impressed me has been the decided lowering of the mortality during the last two decades. The three main causes of death have been shock, hemorrhage and sepsis. These have been overcome by the methods outlined in the paper: namely blood transfusions, chemotherapy and antiseptic vaginal applications. In my mind blood transfusions have played the most important role. I have treated 6 women with inversion of the uterus. The placenta of 1 patient was removed immediately after the accident occurred and the uterus was reinverted manually, a very simple procedure in my hands followed by immediate improvement. Three patients had anterior colpo hysterectomy. The fifth patient had an abdominal pan hysterectomy and the sixth a vaginal hysterectomy. Of the 4 patients whose uteri were conserved, 1 subsequently became pregnant. She had had a Spinelli operation and became pregnant about two years later. At eight and a half months of this gestation she spontaneously ruptured the uterus while in her bed at her home. She was delivered by cesarean hysterectomy, with recovery of mother and baby. The danger of rupture of the uterus must be borne in mind in subsequent pregnancy when one is performing the Spinelli operation or any other type of conservative operation for inversion of the uterus.

DR JOHN HUBERMAN, Newark, N. J.: According to a report from the Maternal Welfare Committee of the Massachusetts Medical Society, April 16, 1942, cases of chronic inversion of the uterus are extremely rare, since most patients with uteri that become inverted and are not replaced die of hemorrhage. Vaginal hysterectomy has been the method usually performed

in these cases of chronic inversion, owing to the fact that the uterine body is edematous and chronically infected. However, with the use of sulfanilamide by local application into the peritoneal cavity, the chances of infection have been minimized. In my case it was deemed safe to perform a Spinelli operation, as I felt that we were dealing with a 22 year old patient, when a conservative operation is preferable. Five Gm of sulfanilamide was inserted into the peritoneal cavity and the uterus was replaced in a normal anatomic position. She was discharged on the fourteenth postoperative day and had a normal menstrual period on the twenty fifth postoperative day.

DR CHARLES E McLENNAN, Minneapolis. In reply to Dr Harer's implication that he prefers immediate replacement I would say that I agree with him when circumstances are such that replacement can easily be done by one conversant with the technique. I merely wanted to suggest that in average hands and under ordinary circumstances when there has been some delay in diagnosis the conservative management appears to give much better results. To Dr Coventry who mentioned the high price of the loss of the uterus, I would like to point out that we do not recommend vaginal hysterectomy except for those women who are through with their childbearing period or in whom for some other reason sterilization is desirable. I wish to thank Dr Phaneuf for pointing out the danger of uterine rupture in those uteri which are reconstructed and left in situ.

SOME PHYSIOLOGIC ASPECTS OF THE USE OF SEA WATER TO RELIEVE DEHYDRATION

ROBERT F BRADISH, MD
Lieutenant Colonel M C U S Army

MERRILL W EVERHART, MD
Major M C Army of the United States

WILLIAM M McCORD, MD
First Lieutenant M C Army of the United States
AND

WILLIAM J WITT MD
First Lieutenant M C Army of the United States
NEW ORLEANS

Modern warfare creates a situation whereby frequently small numbers and less frequently large numbers of naval, military or civilian personnel are suddenly cast on the seas to survive as best they can in small life craft. World War I saw submarine warfare initiated on a major scale for the first time. The present war, however, sees submarine activities and mine laying, together with the proved additional deadly instrument of aerial attack, all conducted simultaneously on the seven seas on a scale hitherto unknown.

Survival at sea after forced abandonment of a ship in an intact standard lifeboat is contingent on two major factors (a) timely rescue or (b) the ability to make land. The first factor is self explanatory. The second is controlled by several subfactors (a) ability to combat exposure and exhaustion, (b) the meteorological conditions such as weather, tide, currents and wind, (c) availability of motive power (1) mechanical (engine and sail), (2) man power, and (d) availability of food and water. The factors that can be controlled or influenced beforehand are availability of motive power and availability of food and water. Bulk and weight can quickly impose definite limitations on those two factors.

Dr D W Williams New Orleans extended his cooperation. Released for publication by the War Department Manuscript Board which assumes no responsibility other than censorship for the contents of this article.

Major Everhart of the Department of Pediatrics and Lieutenant McCord associate professor of biochemistry Louisiana State University School of Medicine are on extended leave for army duty.

The time during which man can be deprived of water intake is vastly shorter than that over which he can be deprived of food and maintain life. The old rough general rule three minutes without air, three days without water or thirty days without food applies. If the chances for survival can be widened from the water deprivation limit of three days to the food deprivation limit of thirty days, then indeed is there a tremendous increase of survival odds. There has been more than one instance lately in which men have exceeded the astounding survival epic of Nordhoff and Hall of *Men Against the Sea*. The question has been raised intermittently and with increasing frequency lately as to whether sea water can be used in any way whatever to satisfy the minimum water needs of the body.

PROBLEM OF MAKING SEA WATER POTABLE

What means can be found to solve the problem of making sea water potable under the conditions stated? There are three approaches to this question.

1 *Chemical*—Sodium chloride constitutes almost 80 per cent of the salts present in sea water. The possibility of precipitating the chloride by use of silver or some similar salts is intriguing. However, a precipitation of this type would merely substitute another radical for the chloride ion and would not reduce the salt concentration or osmotic pressure of the sea water. The use of some type of colloidal reaction in which the sodium chloride could be selectively adsorbed has possibilities. However, at present no such substance is available.

2 *Mechanical*—Actual distillation of sea water is, of course, a well established method. However, the bulk and weight involved in such apparatus, together with the furnishing of the required source of heat energy under all conditions, has thus far precluded any satisfactory solution from this angle.

3 *Physiologic*—The physiologic approach involves the use of sea water in some manner that results in a selective absorption of the water without an accompanying absorption of salt. This would involve the concentration of a solution already hypertonic to the blood. Such a concentration would then violate the present accepted principles of osmosis. However, certain tissues of the body are able to concentrate fluids to some extent, and it is not entirely beyond the realms of possibility that sea water could be further concentrated, even though but slightly, by some living membrane.

Sea water is abundantly available under the stated conditions of disaster. It cannot be used orally because the salt present is absorbed and to some extent may act as a cathartic or emetic. However, precise physiologic proof is lacking with regard to the absorption or non-absorption of sea water when taken by mouth. If 100 cc of sea water of a sodium chloride concentration of 3 per cent is absorbed, it will produce an excretion of 150 cc of urine of 2 per cent sodium chloride concentration, resulting in a net loss of 50 cc of water. The concentrating power of the kidney is limited. The renal tubules cannot concentrate the glomerular filtrate beyond a sodium chloride concentration of about 2 per cent.¹ If the sea water was not absorbed, its higher osmotic pressure would result in drawing water into the lumen of the intestine, thereby also creating a net loss. It would be dangerous and not practical under

¹ Goodman Louis and Gilman Alfred. *The Pharmacological Basis of Therapeutics*. New York: Macmillan Company, 1941. p. 630.

ship disaster conditions to attempt subcutaneous or parenteral use, assuming that it was usable. Therefore the only other possible mode of intake might be by rectal instillation. Current theories of osmosis and absorption would indicate that the use of sea water by mouth or by rectum should not differ in its physiologic effect on water balance. However, the colon is known to have certain powers of absorption and excretion. Therefore we wished to prove experimentally whether or not sea water could be concentrated by the colon to make water available to the organism.

A search of the literature² indicates that little experimental work has been done. A word of mouth statement was made by a Mr. Graham³ in 1916, who claimed to have taken 2 gallons of sea water by rectum daily for seven days while fasting and taking no other fluids. He claimed a beneficial result, being free from thirst and hunger at the end of the period, but published no data. Two British naval surgeons, Critchley and Allison,⁴ conducted an experiment on 2 subjects. They instilled 10 ounces of sea water into the rectum

three times at six hour intervals and noted no beneficial results. More recently an experiment was cited⁵ concerning the use by rectal instillation in which negative results were obtained. Lieutenant Pittard⁶ conducted experiments along similar lines and advocated the use of sea water by rectum to combat dehydration, stating that "sea water was less toxic when taken by rectum."

Our current interest in the overall problem raised in connection with the stocking and provisioning of lifeboats on army transports has led to the following study, which it is believed is more complete than any previously conducted.

PROCEDURE

From the practical standpoint several factors had to be considered, viz, ease of administration, optimum amounts for retention and possible local irritative

effects. In addition, certain theoretical factors such as temperature, humidity, body surface area and water loss by perspiration and other routes could be considered. However, in this experiment the fine considerations of temperature and the like were disregarded until it could first be determined whether the method was actually feasible.

Three army medical officers volunteered as subjects to put the method to a test. In order to simulate conditions of exposure, an island in the Gulf of Mexico, near the mouth of the Mississippi River, was selected as the location for the experiment. The subjects exposed themselves to wind and weather on the shore of the island and reduced their water intake until the symptoms of water deprivation were becoming severe, as noted by subjective observations and by urine analyses. Thus dehydration was established before the experiment was started. Such a state is essential to accurate observation. Sea water for the experiment was obtained from a point 5 miles from the shore of the island and filtered before use. This sea water was somewhat diluted by river water. Its salt content (17 per cent sodium chloride) was approximately half that of open ocean water. A comparison of the effects of this somewhat diluted sea water was to be made later with the effects of sea water of higher saline content. For this purpose a hospital patient was made available for the experiment. As the result of a complete structure of the rectum associated with venereal lymphogranuloma, this patient had received a colostomy several weeks previously at about the midtransverse colon. At the time of operation the colon appeared normal. This patient was in a state of water balance.

METHODS

After a condition of water deprivation was established, filtered sea water was instilled through the rectum into the colon through a soft rubber catheter. Samples were removed at various intervals and analyzed for chloride content by the Schales⁸ method. Urine specific gravities were measured by use of a clinical urinometer. The water in the diet was kept to a minimum by weighing the food and calculating the water content by the use of food charts. The sea water was analyzed for total solids, sodium, magnesium, calcium, carbonate, chloride and nitrate by standard laboratory methods.

With regard to the colostomy patient, 200 cc of the diluted sea water was introduced into the completely divided distal portion of the colon. This obviated any complication involving loss of water or contamination.

7 It has been established that the salinity of ocean water varies in different parts of the world. Pending receipt of samples for analyses from various parts of the Caribbean area no definite figures can be published for this reason. Wheeler's figures are on samples taken off the coast of the Carolinas.

Concentration of Salts in Parts per Hundred

Constituent	Ocean Water	Gulf Ocean Water as Used
Sodium	1.1049	0.5929

by feces. This limited the absorption to this portion of the intestine. Two cc samples were withdrawn every ten minutes for sodium chloride determinations. At the end of one hour the entire contents of the colon were removed and the volume measured. The experiment was repeated three days later, using an artificial sea water solution containing 3.3 per cent of sodium chloride.

RESULTS

SUBJECT 1—The specific gravity of the urine before rectal instillations were commenced was 1.035. The blood nonprotein nitrogen was 40 mg per hundred cubic centimeters. Six hundred cc of sea water was introduced into the bowel through a soft rubber catheter. It was retained with difficulty, because of severe cramping, for six hours. At the end of this period 150 cc of semisolid fecal material was recovered with a total chloride content of 0.6 Gm (0.4 per cent). Two hundred and sixty cc of urine with a specific gravity of 1.027 was passed at the end of the six hour period.

SUBJECT 2—Six hundred cc was instilled into the colon but because of severe cramping could not be retained.

The specific gravity of the urine of the same subject twelve hours later was 1.033 before instillations were commenced. The blood nonprotein nitrogen was 35 mg per hundred cubic centimeters. Three hundred cc of sea water was taken by rectum through a soft rubber tube. Samples of 5 cc volume were taken every twenty minutes for two hours and analyzed for the chloride content. The results are indicated in the accompanying chart. The last sample was obtained with difficulty, as very little fluid remained in the bowel. One hundred and twenty cc of urine was passed at the end of the period, with a specific gravity of 1.021.

SUBJECT 3—The specific gravity of the urine before instillation of 600 cc of sea water was 1.035. The blood nonprotein nitrogen was 34 mg per hundred cubic centimeters. The water was retained one hour and then passed, owing to severe cramping. The volume was 650 cc, which included fecal material. This total sample at the end of the period contained 8.34 Gm of sodium chloride, 1.28 per cent.

Twelve hours later, before instillation was started, the specific gravity of the urine was 1.038. Three hundred cc of sea water was instilled. Samples were taken every twenty minutes. At the end of the period the specific gravity of the urine was 1.032. No residue could be recovered from the bowel at the end of the experimental period.

In none of the subjects was a diminution of thirst apparent after taking the sea water instillations. Headache, weakness, and fogging of mental processes seemed to progress as the experiment continued. Weight loss and anorexia increased. Blood pressure, pulse and temperature were unchanged. The experiment was concluded on May 19, 1942 because analyses were showing that sodium chloride was being absorbed and, with the progressive subjective deterioration, further prolongation of the experiment was not warranted, owing to the possibility of injury to the subjects.

SUBJECT 4 (the colostomy patient)—After instillation of 200 cc of saline solution over a period of one hour the sodium chloride concentration was reduced from 3.3 per cent of sodium chloride to 1.7 per cent of sodium chloride. During this time 40 cc of water was absorbed, as indicated by the recovery of 160 cc of fluid. When 200 cc of 1.7 per cent sodium chloride was used, the concentration was reduced to 1.17 per cent of sodium chloride over a period of one hour. There was recovered 80 cc of fluid, indicating that 120 cc of solution had been absorbed. The patient experienced no discomfort.

As can be seen in the chart, the sodium chloride concentration was diminished in every case both in states of dehydration and in normal hydration.

COMMENT

According to physiologic views, the site of water and salt absorption is in the distal portion of the small intestine and the colon. It would seem then that, regardless of into which end of the alimentary canal salt water was introduced, there would be little if any difference in the physiologic effect. The drinking of sea water results in the absorption of salt as a hypertonic solution and will necessitate the excretion of the salt eventually at the expense of body fluids. This excretion will be through the kidneys, as pointed out previously.

In a normal state of hydration the drinking of sea water will result in an extra loss of fluid with a subsequent dehydration. In a state of dehydration with the absorption of hypertonic salt water, there would be a tendency for sodium chloride to accumulate in the tissue spaces. The osmotic pressure of the extracellular tissue fluid being increased would remove fluid from the tissue cells themselves and from the blood stream. If administration of salt water is continued in the face of progressive dehydration, a state of edematous dehydration would occur. With the loss of fluids from the blood stream and hemoconcentration, a dangerous state of extrarenal azotemia is produced.

We have shown experimentally that sodium chloride as contained in sea water is absorbed from the colon. This is in agreement with the findings of Pittard.⁹ However, our views as to the benefits incurred by this procedure are in absolute disagreement with those who advocate its use. We are convinced that the use of sea water per se by this means would not only not prolong life but would indeed actually hasten death.

The only further line of investigation that appears to be open is conceivably the use of salt free rations in conjunction with an amount of diluted sea water containing salt equal to that amount omitted from the rations. This problem of the use of salt free rations is being investigated.

SUMMARY AND CONCLUSIONS

It has been shown by both subjective and objective observations that the colon will not concentrate sea water and thus make water available to the organism. Therefore, by the same token, rectal instillations of sea water will not alleviate the symptoms of water deprivation.

Office of the Port Surgeon, New Orleans Port of Embarkation

Laws of Osmotic Pressure—Van't Hoff's laws of osmotic pressure may be simply stated. 1 The osmotic pressure of a solution varies directly as the concentration of the solution and is equal to the pressure the solute would exert if it were a gas in the volume occupied by the solution, if the volume of osmotic molecules relative to volume of solvent be negligible. 2 The osmotic pressure of a solution varies directly as the absolute temperature in just the same way as the pressure of a gas varies when its volume is kept constant. These laws of osmotic pressure which were deduced from Pfeffer's data by Van't Hoff have been thoroughly verified by the more accurate observations of Morse and of Berkley and Hartley. As is the case with gases, the laws of osmotic pressure hold closely only for dilute solutions. Appropriate corrections must be made for concentrated solutions.—West, Edward S. *Physical Chemistry for Students of Biochemistry and Medicine*. New York, Macmillan Company, 1942.

REFLEX PULMONARY ATELECTASIS

GEZA DE TAKATS, M D

G K FENN, M D

AND

E L JENKINSON, M D

CHICAGO

Pulmonary atelectasis has important surgical, medical and roentgenologic implications. While there are many theories regarding the production of atelectasis, it is generally agreed that its essential cause is the obstruction of a bronchus with massive secretion.¹ The weakened respiratory force and the accumulation of bronchial mucus, owing to insufficient movement of cilia together with a suppressed cough reflex, are sufficient causes to explain postoperative atelectasis in the opinion of most observers.²

that of the diaphragmatic splint,³ vasodilation with bronchial edema⁴ and bronchoconstriction.⁵ All three theories were discussed and discounted by Coryllos and Birnbaum.²

Recently in studying the widespread autonomic reflexes which originate from the obstruction of the pulmonary artery we became impressed with the effects of pulmonary embolism on the heart,⁶ on the pulmonary arterial tree⁷ and on the bronchi.⁸ It was emphasized in these communications that the mortality and morbidity of pulmonary embolism is not due alone to the mechanical plugging of the pulmonary artery but to the reflex effects on the other thoracic viscera. Among other observations the reactivity of the bronchial tree to the stimulus of pulmonary embolism was striking. Based on animal experiments and correlated with clinical observations it is our feeling that the initiation of the bronchial obstruction may be due to early broncho-

motor and bronchosecretory phenomena which may subsequently result in mechanical obstruction. If this is unrelieved, parenchymal damage will result.

EXPERIMENTAL
EVIDENCE

One can readily demonstrate in the dog that the bronchial tree, visualized by the intratracheal instillation of a radiopaque medium,⁹ invariably goes into spasm when pulmonary embolism is produced by a suspension of equal amounts of barium sulfate, ferric chloride and isotonic solution of sodium chloride (fig 1). The decided change in the pattern of the bronchi is not brought about by dyspnea, lack of sufficient oxygen or increase in carbon dioxide, as a clamp applied to the trachea of the dog fails to produce it. Bilateral vagal section, however, inhibits broncho-

spasm (fig 2). A sufficient dose of intravenous atropine sulfate prevents its occurrence in 60 per cent of the experiments (fig 3). The addition of papaverine to

Fig 1—These films represent two sets of experiments A and B. The bronchograms were obtained five minutes after an intratracheal injection of a radiopaque⁹. The trachea and the larger bronchi are visualized. The upper bronchi are completely filled. In A the lower bronchus did not fill at all. In B the films were obtained immediately after the production of a pulmonary embolus. An equal mixture of ferric chloride, barium sulfate and isotonic solution of sodium chloride was injected intravenously. The opaque material has been squeezed out of the large bronchi into the terminal radiicle. The main bronchi are invisible. In C the third series of films were taken ten minutes after the production of the embolus. The pattern has remained the same. There seems to be some pooling of the opaque material around the middle lobe in C. There are patches of emphysema in C in both the upper and the lower lobe possibly due to incomplete bronchial obstruction.

But ever since the first descriptions of this interesting postoperative or post-traumatic complication the suggestion has been made that reflex nervous stimuli play a part in the initiation of bronchial obstruction. In fact, three different reflex mechanisms were proposed

Fig 2—The effect of bilateral vagal section on the bronchial pattern following embolism. *A* control film showing good visualization of the upper bronchus. *B* film obtained two minutes after bilateral vagal section. The upper main bronchus seems more relaxed and its branches are wider than in the control film. *C* was obtained three minutes after the production of the embolus showing no change in the pattern or caliber of the bronchial tree. *D* was taken ten minutes after the production of the embolus. The original pattern has been maintained. Compare this film with *C*₁ and *C*₂ of figure 1.

Fig 3—*A* control film. *B* film obtained after the intravenous injection of atropine $\frac{1}{2}$ grain (0.0008 Gm) and papaverine $\frac{1}{2}$ grain (0.03 Gm). *C* film taken immediately after the production of an embolus. The bronchial pattern has been maintained. *D* film taken four minutes after the production of the embolus. There is no evidence of bronchial spasm.

powerful coronary vasodilator¹⁰ and inhibits ventricular fibrillation¹¹. Both of these cardiac effects greatly improve the mortality of pulmonary embolism.

Evidence has also accumulated to show that, associated with a reflex bronchoconstriction, an increased bronchial secretion occurs in the experimental animal.⁶ This is to be expected, as the vagal stimulation, which manifests itself in our previously published electrocardiograms and bronchograms, also results in bronchosecretion. We have, then, the essential factors in the production of atelectasis, namely obstruction and increased secretion. Whether contractions and secretion of the bronchus lead to collapse or overdistention of the lung depends on the force of inflation and the time allowed for deflation. As is shown in the clinical films, the high, splinted diaphragm and the hypoventilation of the affected side favor atelectasis instead of emphysema, but the latter is known to occur in pulmonary embolism.¹²

Having shown that pulmonary embolism constitutes a sufficient stimulus for bronchoconstriction and broncho-

Fig 4—From left to right and from above down. The first film is the bronchial tree visualized in the usual manner. The second film shows the pattern after opening of the abdomen. The pattern is essentially unchanged except for a better filling of the bronchi in the lower lobe. The third film was obtained immediately after energetic traction on the cystic duct. The next film was taken three minutes and the last film was taken ten minutes after traction. Note the pronounced scattering in the last film resembling the one obtained after pulmonary embolism. No large bronchi are visible in this film. Judging from the narrowed intercostal spaces and the poor aeration of the lung the chest seems to be fixed in expiration or atelectasis is present.

secretion, we were interested in finding other stimuli which affect the bronchial tree equally. Of various intra-abdominal manipulations, traction of the cystic duct and pulling on the mesentery gave an equally convincing bronchial pattern (fig 4). This change in pattern was again inhibited by the use of atropine (fig 5).

Blunt injury to the chest wall with or without rib fracture gives a spasm of the bronchial tree, which again can be prevented by the administration of $\frac{1}{2}$ grain (0.01 Gm) of atropine in half of the cases (figs 6 and 7).

The demonstration that at least three distinct stimuli, namely pulmonary embolism, intra-abdominal manipulation and trauma to the chest wall, were capable of changing the caliber and pattern of the bronchi warranted a search for such phenomena in patients. It should be noted in the accompanying table that the effect of all these stimuli was modified by the use of atropine.

Fig 5.—Left film Upper bronchus visualized Atropine $\frac{1}{2}$ gram (0.01 Gm) has been injected intravenously Middle film traction on the cystic dust produced no change in the pattern Right film pattern unchanged after ten minutes The atropine seems to have blocked the reflex bronchospasm originated from abdominal manipulation

CLINICAL OBSERVATIONS

Interpretation of the roentgen studies on patients in the light of the experimental work brings us a bit into the field of speculation. At the same time, we believe that the experimental work finds confirmation in the films of patients.

We have been taught in the past to look for a funnel shaped or triangular shadow as evidence of an infarct following pulmonary embolism. We were taught that the infarct was primarily of circulatory origin and was likely to become infected and run the course of a pneumonia, or that an abscess was likely to form at the site of the infarct. All these things do occur, but it has recently been pointed out that triangular infarcts are rare,¹³ and this is certainly borne out by our investigation. It is our belief that if the x-ray shadow that follows pulmonary embolism is due to reflex pulmonary atelectasis, then there is no good reason why the shadow should be triangular or funnel shaped. Furthermore, we believe that if the bronchial obstruction is due to

Fig 6.—The control film on the left shows good pattern of the lower bronchus. The film in the middle was obtained immediately after blunt trauma to the opposite chest wall resulting in fractured ribs. The film to the right was taken ten minutes after the trauma to the chest. The opaque material is scattered and not even smaller bronchi are visible.

reflex constriction and if this constriction can be relieved, there is no good reason why the patient should have a pneumonic episode. The patient's defervescence often corresponds with the time of sudden massive expectoration of bloody mucus, which makes the course

of the infarct look suspiciously similar to that of an atelectasis. On the other hand, patients with pulmonary infarcts who exhibit a lengthy course of fever obviously have pneumonia or a lung abscess at the site of the infarct. In a case of reflex atelectasis the decisive factor in the course of events is whether or not the bronchial obstruction is relieved. The relief of this bronchial obstruction should be one of the therapeutic aims.

From a roentgenologic point of view, the diagnosis of pulmonary embolism is seldom possible. The triangular infarct is seldom seen. In the first twenty-four hours nothing but the high-splinted diaphragm on the involved side may be evident (fig 8). In two to three days an area of consolidation appears which may be pneumonic or atelectatic (fig 9). The patient made a complete clinical recovery within six days under appropriate medication and without the use of the sulfa drugs. Under the circumstances, it is difficult to escape the conclusion that the consolidation here was atelectasis and not pneumonia. The patient whose chest is shown in figure 10 had the clinical symptoms of pulmonary

Fig 7.—The effect of trauma to the chest in an atropinized dog (read from left to right and from above down). The first film was obtained five minutes after the intratracheal injection of a radiopaque oil. The next film was obtained after the dog was atropinized with an intravenous injection of $\frac{1}{2}$ grain of the drug. The third film was taken immediately after a severe trauma to the chest producing fractured ribs. Note again the scattering of the opaque solution due to the mechanical effect of the injury. The outline of the bronchi however is still present. The fourth film shows a maintenance of this residual pattern three minutes after the injury. The last film was taken ten minutes after the injury. In the last three films atelectasis of the upper lobe is increasingly evident. The atropine produced a partial protection none against the shattering effect of the blow.

embolism three days prior to the day the film was made. Yet, in five days (fig 11) the consolidation had almost disappeared. We believe that this points to atelectasis as the cause of the shadow. Without clinical data the radiologist should not be expected to make a diagnosis of pulmonary embolism.

We have described elsewhere what we consider to be the appropriate treatment of pulmonary embolism. Atropine and papaverine play an important part in it. The use of atropine in the presence of bronchial obstruction and hypersecretion may be objected to by many who feel that this drug increases the viscosity of the bronchial mucus and hinders evacuation. However, in the first few minutes and hours following pulmonary embolism atropine dilates the bronchi, as shown in our experimental films, and suppresses secretion. We now have data on 28 patients suffering from pulmonary

13 Hampton A. O. and Castleman B. Correlation of Postmortem Chest Teleroentgenograms with Autopsy Findings. *Am J Roentgenol* 43: 305, 1940.

embolism in whom the atropine-papaverine mixture was administered three times a day for three days. No massive atelectasis was seen in this group, indicating that the medication could not have increased the bronchial obstruction to a harmful degree.

Reflex Bronchial Spasm Summary of Experiments

Method of Production	Number of Dogs	Method of Bronchial Spasm Prevention	per Cent
Pulmonary embolism	13	None	100
	37	Atropine or atropine papaverine	42.5
	4	Bilateral vagotomy	0
Abdominal manipulation	10	None	100
	10	Atropine	30
Trauma to chest	10	None	60
	10	Atropine	30
Total animals used	93		

The second form of reflex atelectasis, namely that occurring during surgical procedures, has now been reported several times. At the Research and Educational Hospitals Dr. W. E. Cassels has observed and studied it on several occasions. Of the many factors

ment¹⁵ Westermarck thought that hemorrhages into and around the bronchi may cause bronchostenosis or atelectasis. Our observations would again suggest that there may be a nervous reflex involved in some of these obstructions, and instead of strapping the ribs and augmenting hypoventilation the painful ribs should be injected with procaine hydrochloride, as Harmon and his associates¹⁶ do, and ventilation encouraged. This, of course, does not apply to the group suffering from a hemothorax or interstitial emphysema.

COMMENT

The experimental findings of a reflex bronchoconstriction and bronchosecretion following pulmonary embolism fit in with the early clinical and roentgen observations in man. But this concept also has a far broader significance in regard to the production of atelectasis in general. If the embolic atelectasis is originated by a nervous reflex, why could not the surgical or the traumatic atelectasis be initiated by the same mechanism? Our animal experiments indicate that this is at least a possibility.

Since 1919 Cutler¹⁷ has repeatedly stated his belief that the majority of postoperative complications are

Fig. 8—Portable film obtained ten days after a hysterectomy, six hours after the onset of a sudden chest pain and dyspnea. Note the elevation of the diaphragm on the right, a perfectly aerated, perhaps even slightly emphysematous, right lower lobe.

Fig. 9—Portable film obtained two days after the film shown in figure 8 was taken. While clinically the patient ran the typical course of a pulmonary infarct with phlebitis, bloody sputum and diaphragmatic pain, the film shows an atelectasis of the right lower lobe with a splinted high diaphragm and narrowed intercostal spaces. Such patients often show right upper rectus rigidity simulating gallstone colic.

Fig. 10—Film obtained fourteen days after an electric resection of the prostate. The patient had chills and fever and was first thought to have a tumor of the right upper lobe. Embolism was diagnosed as a phlebitis and rusty sputum later developed.

which may be responsible for such an occurrence might be mentioned: insufficient premedication with atropine or scopolamine, too light an anesthesia, trauma at intubation, position of the patient and possibly the parasympathetic action of cyclopropane.¹⁴ In the individual case it is rarely possible to accuse any single factor for the atelectasis. By observing the expansion of the two chest walls, massive atelectasis can be detected easily and aborted by hyperventilation and suction by catheter. Quite recently one of us (G. de T.) observed atelectasis of the right upper lobe within a few seconds after the surgical closure of an arteriovenous fistula. It is well known that such a closure produces vagal phenomena such as bradycardia.

Traumatic atelectasis deserves more recognition than it has received in the past. When contusions of the chest wall are thoroughly studied with roentgen rays some evidence of pulmonary change has been observed in roughly three fourths of the cases. When fractured ribs were present 86.7 per cent of the patients had roentgen changes in the lungs, while in the absence of fracture 65 per cent showed some pulmonary involve-

ment. He excluded the massive field. He excluded the massive fatal emboli and stressed the patches of consolidation around small thrombi. This theory now receives experimental support. On the basis of our present observations, we would assume that such thrombi produced reflex bronchial spasm and secretion to account for the consolidations.

We do not wish to imply, however, that a small embolus is necessarily present in all cases of reflex atelectasis. Gilbert, Fenn and LeRoy¹⁸ have shown that abdominal stimuli can produce reflex cardiac effects which are due either to vagal stimulation or to sympathetic inhibition. While ether is known to be a bronchial dilator, some anesthetics, such as cyclopropane, may facilitate vagal tone. The beginning of atelectasis may often be on the operating table, and the well trained anesthetist is always on the lookout for a unilateral lag

of costal breathing. Hyperventilation with carbon dioxide is easily accomplished at this stage. The Trendelenburg position of recently operated patients is an additional help toward bronchial drainage. That the stimulation of lung or pleura is capable of initiating vagal reflexes is sufficiently known, and the literature of this subject is summarized elsewhere.

Fig. 11.—Film taken four days later. The solid triangular area has almost disappeared. It could not have cleared so fast unless atelectasis was responsible for the consolidation.

It is far from our belief that the form of bronchoconstriction and bronchosecretion discussed here is the only mechanism by which atelectasis is produced. Lobar collapse is well known to occur from peribronchial compression by glands, by tumors or by swelling of the mucous lining around foreign bodies.

That injections of iodized poppy seed oil may occasionally produce spasm followed by atelectasis in normal contractile bronchi was demonstrated in 1929 by Jacobaeus and his associates.¹⁹

SUMMARY

The bronchial tree is capable experimentally of decided contraction and secretion immediately following pulmonary embolism. Clinical and roentgen data show that bronchial obstruction with subsequent atelectasis is a factor in the production of clinical and roentgen findings in pulmonary embolism. Additional data suggest that reflex atelectasis may occur from other sources than pulmonary embolism. Its early recognition and treatment are stressed.

122 South Michigan Avenue

ABSTRACT OF DISCUSSION

DR. LOUIS H. CLERF, Philadelphia: My knowledge of this subject is limited to postoperative pulmonary atelectasis. I have seen and treated many of these cases by bronchoscopy and always have been interested to know why a previously normal bronchus should secrete thick, tenacious secretion in large quantity and why there was an absence of adequate ciliary activity so that the secretion accumulated and ultimately produced bronchial obstruction. This usually was explained in a vague manner as being due to secretory or other disturbances. Possibly de Takats and his associates have given us the explanation. On the basis of their experimental work it affords a reasonable explanation. I am also interested in their reference to atropine and the fact that it probably would inhibit the occurrence of this. I have always advocated no atropine because it increases the viscosity of secretions and diminishes the quantity.

DR. G. K. FEHN, Chicago: Atropine doesn't seem to do any harm. The theory behind the atropine is to block off the vagal effects which produce bronchial constriction. At the same time it might be expected that this would cause more viscid mucus, but, as we cited in the paper, the atropine has been used very liberally, and no untoward results have occurred.

Clinical Notes, Suggestions and New Instruments

SPONTANEOUS RUPTURE OF THE NORMAL SPLEEN

JAMES R. WATSON, M.D., A. D. MURRAY FERDEBER, M.D.
PITTSBURGH

Rupture of the spleen may result from trauma or it may occur spontaneously. Spontaneous rupture is uncommon and usually occurs in the presence of splenomegaly, in most instances the result of malaria or typhoid. It has been reported less frequently during the course of puerperal sepsis, relapsing fever, pneumonia, cirrhosis of the liver, leukemia, typhus and infectious mononucleosis. Several cases have been reported in which it occurred during a normal pregnancy. In a few instances rupture had occurred spontaneously in a healthy individual with a normal spleen. Attempts to explain this phenomenon are confusing and, from a practical point of view, purely academic. Hamilton Bailey dismissed the subject by stating that only the spleen can behave in this curious manner,² a remark reminiscent of Galen who spoke of the spleen as an organ "full of mystery."

The following report illustrates most of the diagnostic problems involved and bears out another of Bailey's remarks: "In traumatic hemoperitoneum in the male examine first the spleen."

REPORT OF A CASE

A white man aged 27 was admitted to the Presbyterian Hospital on the morning of March 23, 1942 because of severe pain under the left costal margin which had awakened him out of a sound sleep seven hours before. The pain radiated up to the left scapula, shoulder and left side of the neck and was accompanied by a sense of oppression and inability to get his breath. He was nauseated but did not vomit. Any attempt to get out of bed increased the severity of the pain to such a degree that it was two hours before he was finally able to get up and make his way down one flight of stairs to get help. He fainted at the foot of the stairs where he was found by his landlady. One of us (M.F.) saw him within the next fifteen minutes and physical examination at that time was negative save for pallor of the face which was most pronounced about the lips, rapid pulse and heart sounds which were of poor quality and slightly irregular in rhythm and intensity. The blood pressure was 118 mm. of mercury systolic and 70 mm. diastolic. Examination of the abdomen was entirely negative. Coronary occlusion was thought to be the most likely diagnosis so a hypodermic of an antispasmodic preparation was administered and arrangements were made to take the patient to the hospital.

The past medical history was entirely negative except for some of the exanthemas of childhood. He had been dismissed from the Army three months before the onset of his illness in order to permit him to return to his former office position as an essential employee in a war industry. He had had no injuries of even a minor nature that he could recall, and his sedentary life since leaving the Army had not subjected him to any trauma or excessive exertion.

The only additional physical abnormality on admission to the hospital was the presence of ecchymosis on the dorsum of the right hand, on the right elbow and about the left eye, apparently the result of the fall. The patient was comfortable as long as he lay quietly in bed. An electrocardiogram taken shortly after admission failed to show evidence of degenerative change, although a slight elevation of the RST interval in leads 2 and 3 was considered a possible early indication of a myocardial infarct. A roentgenogram of the chest taken with a portable machine was negative. The blood count was reported as 4,210,000 red blood cells and 20,650 white blood cells per cubic millimeter of blood. The hemoglobin was 84 per cent. There were 68 per cent polymorphonuclears, 29 per cent lympho-

¹⁹ Jacobaeus, H. C., Selander, G. and Westermarck, N. A Study of Acute Massive Atelectatic Collapse of the Lung. *Acta med. Scandinav.* 71: 439, 1929.

From the Presbyterian Hospital and the Department of Surgery of the University of Pittsburgh School of Medicine.

cytes and 3 per cent monocytes. The urine was negative save for a trace of albumin.

The symptoms again became somewhat more severe in the afternoon and, for the first time, signs suggestive of an intra-abdominal lesion began to appear. These consisted of point tenderness on deep palpation in the epigastrium just to the right of the midline and rebound tenderness to a slight degree over the lower part of the abdomen. There was no rigidity, distention or discoloration. One of us (J. W.) was asked to see the patient on surgical consultation, and on the basis of the history and the aforementioned conditions a presumptive diagnosis of a perforated peptic ulcer was made. The roentgen examination was repeated with the patient in the upright position in an effort to detect the presence of gas beneath the diaphragm, but this was entirely negative, nor was there any tenting of the diaphragm suggestive of fluid. The findings were nevertheless considered sufficiently positive to warrant abdominal exploration, and this was carried out sixteen hours after the onset of symptoms.

Under spinal anesthesia, later supplemented by cyclopropane, an upper midline abdominal incision was made. As the incision reached the peritoneum blood could be seen through it. A plasma transfusion was started and the abdominal cavity was opened, revealing a large amount of liquid blood which obscured everything and which was estimated to amount to about 1,500 cc. Three hundred cc was removed, and then the procedure was abandoned as useless, as it seemed to make no impression on the amount remaining. The liver or the spleen was thought to be the most likely source of the hemorrhage. The liver was perfectly normal on palpation, but when the hand was inserted into the upper left abdominal quadrant a large hematoma was felt at the lower pole of the spleen. The spleen felt to be of normal size, was in its normal position and was not adherent to the diaphragm. Splenectomy was performed and the incision was closed in anatomic layers without drainage. The patient had received 500 cc of plasma during the operation and left the operating room in fair condition with a pulse rate of 120 beats a minute and a blood pressure of 160 mm of mercury systolic and 70 mm diastolic. Five hundred cc of whole blood was given shortly after operation and this was repeated the following day.

Fig 1—Sagittal section of the spleen showing the area of hemorrhage near the inferior pole. The anomaly is demonstrated by the presence of a glass rod to the right of the midline and by a defect in the tissue to the left.

The day after operation the blood count had dropped to 3,430,000 red blood cells per cubic millimeter of blood and the hemoglobin to 68 per cent the following day to 3,150,000 red blood cells and 65 per cent respectively. After the second transfusion the counts began to rise again and at the time of discharge from the hospital there were 4,860,000 red blood cells

per cubic millimeter of blood with 89 per cent hemoglobin. Blood platelet counts, repeated at intervals, were well within normal limits. The Kline test gave a negative reaction.

The spleen measured 11 by 8 by 3.5 cm. There was an anomaly present in the form of a capsule-lined slit 1 cm in width which extended through from the diaphragmatic to the hilar surface. The capsule was absent from about one half

Fig 2—A small artery showing intimal thickening and irregular hyalinization of the wall $\times 400$.

of the inferior diaphragmatic surface. There was a small blood clot under the edge of the remaining capsule, and on cut section this was seen to extend into the splenic pulp along the course of a blood vessel. There was no connection between the anomaly and the site of hemorrhage. On microscopic study the arteries were found to show thickening of the intima and hyalinization of the walls. The sinuses were somewhat dilated and showed the presence of an occasional polymorphonuclear cell. There was some trabecular and capsular fibrosis.

The patient made an uneventful recovery and left the hospital eighteen days after admission. Two weeks later he returned to his home in a neighboring state to continue his convalescence. While there, he was in bed for two weeks with intermittent fever, headaches and cloudy urine which the family physician said was due to the presence of blood. This syndrome gradually subsided, and when next seen two months after operation he appeared to be in excellent health and stated that he felt fine. Physical examination as well as a blood count and urinalysis at this time were negative. He has returned to work and is symptom free except for slight fatigue which is gradually disappearing.

COMMENT

In most of the cases reported in the literature an operation was performed under the impression that the signs and symptoms were the result of a perforated peptic ulcer although in a few women in whom pregnancy was suspected the preoperative diagnosis had been ruptured ectopic pregnancy. Localization of the pain in the epigastrium and radiation to the shoulder have not always been present as they were in this case, making the differentiation between an upper and a lower abdominal lesion difficult at times. The most important factor is the early recognition of an intra-abdominal lesion and operation as soon as possible. While the lesion is not common, Bailey's aphorism might be recommended with profit to any one who does emergency abdominal surgery.

Special Article

HANDBOOK OF NUTRITION XII

FOODS OF PLANT ORIGIN

LEONARD A. MAYNARD, PH.D.

ITHACA, N. Y.

These special articles on foods and nutrition have been prepared under the auspices of the Council on Foods and Nutrition. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the Council. These articles will be published later as a Handbook of Nutrition.—Ed

Over 50 per cent of the American diet consists of foods of plant origin. Indirectly as foods for animals, plant products make an additional contribution to the human diet through their influence on the nutritive value of animal products.

In discussing nutritive values, it is necessary to make use of certain average figures for nutrient composition. Foods of plant origin are subject to rather wide variations in composition as influenced by genetic, soil and climatic factors. It is beyond the scope of this article to consider these factors. Their importance is illustrated by the study of Schultz and his co-workers,¹ revealing wide variations in the thiamine content of wheat and of cereal grains of different origin. Some of the factors influencing mineral nutrition have recently been reviewed by Maynard² and by Beeson.³ Fortunately the consumer seldom gets his supply of a given food from a single agricultural source, and thus the significance of the wide variation in the composition of crops differently produced is not nearly so great as the individual values might suggest. There are also variations in foods as consumed caused by processing, storage and cooking factors. In the present article attention is called to these factors if they have a particular bearing on the significance of the average values cited. For convenience of discussion, the foods of plant origin are grouped as follows: cereals, legumes and nuts, potatoes, other root crops, tomatoes, leafy vegetables, miscellaneous vegetables, fruits, sugar, syrups and molasses and vegetable oils.

CEREALS

Under cereals are included the cereal grains and their products, including flour, bread, breakfast foods, crackers, cookies, pastry and macaroni. Because of the low cost of cereals in relation to most other foods, then consumption is largest among the low income groups. The importance of these foods in the diet has been set forth editorially in *THE JOURNAL*⁴ as follows:

The cereal grains are the backbone of the nutrition of most of the races of the earth. They are, as a rule, the cheapest sources of food fuel, so that corn, wheat, rice, rye, barley and oat kernels are to be found constituting a third or often much more of the calory intake of the millions of persons involved.

Cereals also provide a third or more of the protein of the American diet. While this protein is not so high in biologic value as that of animal products, combina-

tions of cereal and animal protein provide a diet of excellent protein quality. Important amounts of phosphorus, iron, copper and other minerals and of certain vitamins are supplied by cereals. Generalizations here are of limited value, however, because of the differences among cereals and the losses which result on milling.

Wheat—Wheat is by far the leading cereal in the diet in the United States, furnishing approximately 25 per cent of the total calories consumed. The total per capita flour consumption for 1941 is estimated at 155 pounds (70 Kg.), 97 per cent of which was the milled product, leaving less than 5 pounds (2 Kg.) as whole wheat or graham flour. The consumption of wheat breakfast foods approximated 1½ pounds (0.7 Kg.) per capita. The proximate composition of the flours, as listed by Chathfield and Adams,⁵ is presented in table 1.

It is clear that wheat makes a substantial contribution to the protein needs of the diet. Using the percentage figure for patent flour, one may calculate that the average daily consumption of 6¼ ounces (225 Gm.) of flour supplies 22 Gm. of protein daily, or nearly one third the daily allowance. Whole wheat contains more protein than white flour, and its protein has a higher biologic value, but when white flour is supplemented with milk, eggs or meat, a protein mixture of high biologic value results. The much lower fiber content of patent flour reflects the removal of the bran in milling. While bran contributes laxative qualities to the diet, it is poorly digested and may be somewhat irritating to the mucous membranes of the digestive tract. The physiologic effects of bran have been reviewed by the Council on Foods.⁶

In table 2 are presented the vitamin and mineral values of whole wheat and white flour and, for comparative purposes, the minimum values set by the United States government for enriched flour. The values for thiamine, riboflavin, nicotinic acid and iron are taken from Ferrari.⁷ Those for pantothenic acid and pyridoxine were supplied by Elvehjem.⁸

The large milling losses of vitamins and minerals are evident from this table. The data show that the outstanding superiority of enriched flour over ordinary white flour lies in its fivefold increase in thiamine content, the figure being 75 per cent of that for whole wheat flour. On the other hand, the enrichment in nicotinic acid and iron is small compared with the amounts present in whole wheat flour. The data show that milling results in a 60 per cent loss of pantothenic acid and a 50 per cent loss of pyridoxine. Much of the phosphorus and certain other minerals is also lost.

The enriched flour now on the market is nearly all produced by adding the nutrients in question to the refined product. A somewhat similar result can be achieved by "longer extraction" in milling, that is by retaining some of the vitamin and mineral rich portions of the wheat which are milled out in making patent flour. This is the procedure officially adopted in Canada, as described by Tisdall and his associates⁹ and by Newman.¹⁰

10 Newman L. H. The Retention of B Vitamins in Flour and Bread. *J. Am. Soc. Agronomy* 34: 109 (Feb.) 1942.

Wheat flour is consumed to a large extent in the form of bread, of which 85 per cent is commercially baked. Most of this bread is made from white flour, but it is estimated that approximately 35 per cent of the bread now consumed is the enriched product. This enriched bread is obtained either by the use of enriched flour or enriched yeast or by the direct addition of the specified minerals and vitamins to the dough.

An important factor in the nutritive value of bread is the extent to which skim milk solids are used in its manufacture. Six per cent of these is mentioned as

TABLE 1—*Proximate Composition of Whole Wheat and of White Flour*

	Protein per Cent	Fat per Cent	Carbo- hydrates, per Cent	Crude Fiber per Cent	Fuel Value per 100 Gm Calories
Wheat flour, graham	13.0	2.0	72.4	1.8	360
Wheat flour, patent	10.8	0.9	73.9	0.3	340

the desirable amount in modern bread, but apparently much bread is made with 3 per cent or even less when the cost of skim milk is high. Whole wheat bread is commonly made without milk solids. The inclusion of 6 per cent of the solids increases the calcium content of white bread four times and the phosphorus content twice and adds 60 micrograms of thiamine and 360 micrograms of riboflavin per pound. It also improves the protein value considerably.

The proposed minimum standards which are now being followed for enriched bread are, per pound, thiamine 1 mg, riboflavin 0.8 mg, nicotinic acid 4 mg and iron 4 mg.⁷ A similar content of skim milk solids being assumed, the thiamine content is approximately three times as large as that of ordinary bread, the iron content is doubled and the nicotinic acid content is increased slightly. In these and in other nutrients the enriched product falls considerably short of whole wheat bread.

Since whole wheat bread contains the bran which is largely absent in white or in enriched bread, the question of relative digestibility is an important one. This question was thoroughly studied by Rubner¹¹ during World War I. He found that the advantage of the higher protein content of the unmilled product was offset by its lower digestibility and that it contained slightly less total available calories. Noteworthy modern studies have recently been published by Murlin and his associates¹². The first study shows that whole wheat bread has in general a lower protein digestibility value but a higher protein biologic value. The second study reveals no significant differences in the digestibility of the carbohydrates of the two breads. The authors point out that any differences in protein or in available energy values are small and of little importance as compared with differences in vitamins and minerals.

Corn—Corn meal is the chief form in which corn is used as human food, representing a per capita consumption of 23½ pounds (11 Kg) in 1939. An additional 8 pounds (4 Kg) is consumed as breakfast foods, grits, hominy and canned corn.

The corn grain is approximately equal to the wheat grain in thiamine content but contains only one-fourth as much nicotinic acid. It is a good source of phosphorus and iron and certain other minerals. But most of the corn meal and flour consumed, as well as the hominy, grits and breakfast foods, is in the form of milled products. The milling process removes the germ and the bran and thus takes out most of the thiamine and minerals present in the entire kernel. The corn products must therefore be considered to be primarily energy yielding foods. They contain 8 to 9 per cent of protein, which ranks below wheat in biologic value but which combines with milk to provide a protein mixture of high quality. Yellow corn meal differs from the white variety, as well as from other cereals, in containing a significant amount of vitamin A—350 to 500 international units per hundred grams. In view of the rather large consumption of corn meal and other milled corn products by certain groups of the population, the wider use of the unmilled meal or the development of milling methods which would retain nutrients now lost would be highly desirable.

Canned corn is equal to corn meal in energy and protein on an equivalent moisture basis and is superior to the milled product in mineral and thiamine content.

Oats—Among the breakfast food cereals, oatmeal and rolled oats, the principal forms in which oats are consumed, rank first both in quantity eaten and in nutritive value. Approximately 529 million pounds (240 million Kg) is consumed annually. In the milling of oats, only the fibrous hull and the adhering portions are removed, the germ and the other vitamin-rich and mineral-rich portions being left with the product used for human food. Thus oatmeal ranks nutritionally as a whole grain cereal rather than as a milled product.

Oat cereals rank above wheat products both in fuel value and in protein content. Their higher fuel value is due primarily to their fat content (7.4 per cent). Their protein content, of over 14 per cent, outranks that of white wheat flour in biologic value. Both oatmeal and rolled oats are low in crude fiber and when properly cooked are highly digestible.

Oatmeal is considerably richer than whole wheat in thiamine. Aughey and Daniel¹³ reported that one hun-

TABLE 2—*Vitamin and Mineral Content of Flours*

	Whole Wheat Flour Mg./Lb.	White Flour Mg./Lb.	Enriched Flour Mg./Lb.
Thiamine	2.20	0.33	1.66
Riboflavin	0.50	0.13	1.20*
Nicotinic acid	25.00	3.50	6.00
Iron	18.00	3.00	6.00
Pantothenic acid	6.50	2.50	
Pyridoxine	2.15	1.12	

* Requirement suspended at present.

dred and twenty minutes' cooking in a double boiler did not cause any appreciable loss of thiamine from rolled oats. According to Andrews, Boyd and Terry,¹⁴ the riboflavin content of the oat grain averages 0.58 mg per pound. Elvehjem⁸ has found the following values for other vitamins in oats: nicotinic acid 0.45 to 0.68 mg per pound, pantothenic acid 12.2 to 13.6 mg per pound and pyridoxine 0.72 to 0.90 mg per pound.

R. with White Bread. J. Nutrition 22: 573 (Dec.) 1941. Sealock, R. R., Basinski, D. H. and Murlin, J. R. Apparent Digestibility of Carbohydrates, Fats and Indigestible Residue in Whole Wheat and White Breads. ibid. 22: 589 (Dec.) 1941.

¹³ Aughey, Elizabeth and Daniel, Esther P. Effect of Cooking on the Thiamine Content of Foods. J. Nutrition 19: 285 (March) 1940.

¹⁴ Andrews, J. S., Boyd, H. M. and Terry, D. E. The Riboflavin Content of Cereal Grains and Bread and Its Distribution in Products of Wheat Milling. Cereal Chem. 19: 55 (Jan.) 1942.

It seems probable that most of the vitamin content here represented remains in the cereal after milling.

Oatmeal is a rich source of iron (5.2 mg per hundred grams) and copper (7.38 parts per million). Its phosphorus content, 66 per cent of which is in the form of phytin, is similar to that of whole wheat.

Rice—Rice supplies slightly more than 1 per cent of the calories of the average American diet, the annual per capita consumption being approximately 5 pounds (2 Kg). White, or milled, rice, the form in which most of the consumption occurs, is essentially an energy food. The protein content is around 7.5 per cent, thus being lower than that of corn. Over 50 per cent of the minerals and 85 per cent of the thiamine of the entire kernel are lost in milling. In contrast, brown rice, the product that results when only the hull is removed, contains 0.7 to 0.9 mg of thiamine per hundred grams. It is nutritionally superior in other respects also. A change from white to brown rice would certainly be in the interests of better nutrition.

Rye—The consumption of rye, mostly as milled rye flour in bread, is less than 3 pounds (1.3 Kg) per capita annually. This flour is similar to white wheat flour in energy and in protein content. While the whole grain contains approximately 5 micrograms of thiamine per gram on the average, most of it is removed in milling. Minerals are largely removed also. Thus rye flour appears to be similar to white wheat flour in general nutritive value.

Barley—A small amount of barley is consumed as pearl barley and as barley flour for infant feeding. These are milled products which are apparently similar to white wheat flour in energy value but lower in protein content. Milling has removed minerals and vitamins to an extent similar to that in which it removes them from wheat.

LEGUMES AND NUTS

Dry legume seeds, such as beans, peas and lentils, are approximately twice as rich in protein as the cereals. While legume protein is of rather low biologic value when fed alone, its deficiencies are made up by other proteins in a mixed diet. Dried beans, either home cooked or canned, are noteworthy as a cheap source of protein even though the digestibility is somewhat less than for protein from many other sources.

Dried navy and kidney beans, green or dried lima beans, green or dried peas, lentils and cow peas are all rich sources of thiamine, containing around 0.5 mg per hundred grams of the dried seed. A part of this thiamine is lost, however, in the cooking process. Two-thirds cup of baked, canned beans should nevertheless supply one-eighth of the day's thiamine requirement. These legumes also supply significant amounts of riboflavin. Fresh green lima beans and peas are rich in ascorbic acid, but a large loss is involved in cooking. The legume seeds are noteworthy also for their iron content, the dried products containing from 6 to 10 mg per hundred grams. Two-thirds cup of baked beans will supply one-fourth the daily adult allowance. Legume seeds are notably higher in calcium and in phosphorus than are even the whole cereal seeds.

It is evident that a larger consumption of dried legumes, particularly in place of refined cereals, would improve the diet in several respects. Their cheapness commends them especially for use in low cost diets.

Green and yellow string and wax beans, classed as seed pods, are comparable to the legume seeds in pro-

tein, minerals and thiamine per unit of dry matter and in addition contain notable amounts of vitamin A, riboflavin and ascorbic acid.

Peanuts have nutritive values similar to those of the legume seeds previously mentioned and in addition contain vitamin A as well as a much higher energy value. Peanut butter has a nutritive value similar to that of peanuts. Soy beans are apparently nutritionally similar to peanuts, though they are little used as human food. Walnuts are comparable to peanuts in thiamine content, but almonds and pecans have somewhat less. All three have a high fat and a high protein content and are comparable to peanuts as sources of calcium and phosphorus.

VEGETABLES

Under the heading "Vegetables" are grouped a great variety of foods which differ widely in their nutritive values.

Potatoes—According to United States Department of Agriculture statistics, 305,200,000 bushels of white or Irish potatoes were consumed in the United States in 1939, or approximately 138 pounds (63 Kg) per capita. Thus potatoes provide approximately 4 per cent of the total calory needs on the average. For many people, however, particularly the lower income groups, potatoes make up a much larger part of the diet than this average figure indicates, and their nutritive value is of added concern accordingly.

Potatoes are primarily an energy food, consisting largely of starch. Approximately 10 per cent of the total calories are in the form of protein of good biologic value. The potato is low in fiber, and according to various investigators it is highly digestible (92 to 99 per cent being used). It is a significant source of iron, in that one medium-sized potato provides approximately one-tenth the daily requirement.

As harvested, potatoes contain 20 to 35 mg of ascorbic acid per hundred grams and thus provide a substantial amount of this vitamin. There is a continuous loss in storage, however, which amounts to 50 to 70 per cent in twelve months. The initial loss is rapid. There is a further loss in cooking, ranging from 9 to 24 per cent according to the procedure, as reported by Rolfe.¹⁵

The thiamine content of the potato ranges from 95 to 165 micrograms per hundred grams, which would mean from 8 to 14 per cent of the adult daily requirement in a 150 Gm serving (approximately the average daily consumption) if it were not for cooking losses. The potato does not supply a significant amount of riboflavin. There is evidence that the mineral and vitamin content of the potato is richest just under the skin. Thus cooking in the skin means less loss because the skin is removed with less adhering flesh after cooking and because there is less opportunity for solution losses, such as occur in boiling.

The consumption of sweet potatoes in pounds is only about 25 per cent that of the white variety previously discussed, but it is approximately 35 per cent in terms of calories, owing to the higher dry matter content of the sweet variety. Like the white, the sweet potato is primarily an energy food, low in fiber and highly digestible. Only 6 per cent of the total calories are in the form of protein, as compared with 10 per cent for the white variety.

¹⁵ Rolfe, Lydell A. The Effect of Cooking and Storage on the Ascorbic Acid Content of Potatoes. *J. Agr. Sci.* 61: 381 (Sept.) 1940.

Sweet potatoes are especially noteworthy, however, for their vitamin A value. Booher¹⁶ gives a value of 3,460 international units per hundred grams of the cooked product. Thus an average sized serving would supply two-thirds the adult daily allowance of 5,000 international units.¹⁷ Sweet potatoes are apparently similar to white in vitamin C content but lower in thiamine. They are also lower in iron and make no significant contribution to the diet as regards other minerals, except possibly in certain trace elements. An excellent study of the nutritive value of dehydrated sweet potatoes has recently been published by Lease and Mitchell.¹⁸

Other Root Crops—Among other root crops, the carrot is outstanding in nutritive value because of its high carotene content, which ranges from 2,200 to 10,000 international units per hundred grams. Approximately three-fourths cup of cooked carrots furnishes one-third to three-fourths the daily adult requirement. Compared with potatoes, calory for calory, carrots furnish slightly more protein, iron and thiamine, seven times as much calcium, three times as much riboflavin and somewhat less vitamin C.

Compared with the carrot on a calory basis, turnips furnish similar amounts of thiamine, riboflavin, iron and protein, 50 per cent more calcium and eight times as much vitamin C. Swede juice has been reported one-half as rich as orange juice. One-half cup of properly cooked turnips should supply approximately one-fifth the adult daily allowance of ascorbic acid. Beets are similar to carrots as regards riboflavin and vitamin C content and contain more iron and protein. Raw onions are also a good source of vitamin C according to Murphy,¹⁹ but storage losses range from 14 to 50 per cent, and thus old onions are not a reliable source.

Tomatoes—Tomatoes are one of the most important protective foods, both because of their special nutritive values and because of their widespread production. They rank third in quantity among the vegetable crops, being exceeded only by white and sweet potatoes. Among the canned vegetables, the tomato in its various forms ranks first.

Tomatoes are outstanding as a source of ascorbic acid, having an average content of 25 mg. per hundred grams for the summer grown products. Thus one small tomato will supply about one-third the recommended daily allowance for the adult (75 mg.). The acidity of the tomato protects it against any considerable loss in cooking unless soda is used in the process. In the canning of tomatoes and tomato juice there is little loss of the vitamin if the process is properly carried out. One 5 ounce (150 cc.) glass of tomato juice supplies about one-third the daily allowance. Recent evidence indicates that tomatoes as purchased on the northern markets in winter contain much less ascorbic acid than those available in summer.

16 Booher, Lela E. and Marsh, R. L. The Vitamin A Values of 128 Foods as Determined by the Rat Growth Method. Tech. Bull. 802 United States Department of Agriculture, December 1941.

17 In setting up this allowance it was recognized that somewhat more would be required if all the units were furnished as carotene and some what less if all were furnished by vitamin A itself, because a unit in the form of carotene may be under certain conditions at least only about half as effective in human nutrition as a unit of vitamin A itself. Thus the rating here given for sweet potatoes while accurate for comparison with other plant sources of vitamin A overrates the vegetable in comparison with a source of vitamin A itself. The same considerations apply to later discussions of the vitamin A value of the foods included in this paper.

18 Lease, E. J. and Mitchell, J. H. Biochemical and Nutritional Studies of Dehydrated Sweet Potato. Bull. 329 South Carolina Agricultural Experiment Station, June 1940.

19 Murphy, E. F. Ascorbic Acid Content of Onions and Observations on Its Distribution. Food Research 6: 581 (Nov-Dec) 1941.

Tomatoes are also rich in carotene. Ripe tomatoes, fresh or canned, contain approximately 1,000 international units of vitamin A per hundred grams. This means that one small tomato or a 5 ounce glass of canned juice will supply about one-fifth the daily adult allowance.

On the basis of the available figures, tomatoes in the amounts consumed cannot be considered as an important source of any of the B group of vitamins or of the mineral elements with the possible exception of iron.

Leafy Vegetables—The leafy vegetables, including cabbage, kale, chard, broccoli, spinach, turnip greens, collards, lettuce and beet greens, are outstanding sources of certain minerals and vitamins. They are particularly noteworthy for their calcium, the important element in which cereals, potatoes and most other foods except milk and cheese are deficient. Among the leafy vegetables mentioned, turnip greens rank at the top in calcium content. One-half cup (3 ounces, or 90 cc.) of the cooked greens will supply approximately one-third the daily adult allowance. Broccoli, collards, kale, loose leaf lettuce and mustard greens are also rich sources. Head lettuce and cabbage are relatively low, but cabbage greens and the outer leaves of cabbage rank even higher than turnip greens.

Experiments by Fincke²⁰ have shown that the calcium content of broccoli and that of cauliflower are nearly as available as that of milk. Speirs²¹ has reported that the utilization of calcium from turnip greens is about equal to that from milk but that the calcium in tender greens, collards and kale is less well utilized. The calcium of spinach, beet greens, chard and lamb's-quarters is not nutritionally available because of the high oxalic content of these vegetables.

The calcium contribution of green leafy vegetables becomes particularly important in diets containing little milk or cheese.

The green leafy vegetables are important sources of iron. A serving (3 ounces) of cooked turnip greens, mustard greens, spinach, chard or beet greens will supply approximately 25 per cent of the adult daily allowance. Kale supplies somewhat less, and headed lettuce and cabbage are relatively poor sources.

The green leafy vegetables are all rich sources of carotene and thus make an important contribution to the vitamin A content of the diet. Sherman²² gave a range of 13,000 to 27,000 international units per hundred grams for kale, chard, spinach, turnip greens, dandelion greens and mustard greens. The greener and leafier the product, the higher is the vitamin A content. Allowing for losses in cooking and for the fact that the vitamin allowance must be higher when carotene is the source, a 3 ounce serving of one of these greens can be relied on to meet more than the day's needs. Headed cabbage and lettuce are relatively poor sources.

In the fresh state, the leafy vegetables are excellent sources of vitamin C. A cup of raw shredded cabbage will furnish nearly a third of the day's allowance. Watercress, collards, broccoli, turnip greens, mustard greens and kale are similar in vitamin C content to cabbage, beet greens and dandelion greens contain somewhat less, lettuce, escarole and endive contain much less. Leafy vegetables lose vitamin C by oxidation in storage and also in cooking. Further losses occur

20 Fincke, M. L. The Utilization of the Calcium of Cauliflower and Broccoli. J. Nutrition 22: 477 (Nov.) 1941.

21 Speirs, Mary. The Utilization of Calcium in Various Greens. J. Nutrition 17: 557 (June) 1939.

22 Sherman, H. C. Chemistry of Foods and Nutrition, ed. 2. New York: Macmillan Company, 1941.

by solution in cooking if the cooking water is discarded. Gould, Tressler and King²³ found that, in cooking, 25 per cent of the vitamin C of cabbage was destroyed by oxidation and another 25 per cent lost in the cooking water. Other vegetables have shown similar losses. In the preparation of vegetables, further destruction of vitamin C by oxidation occurs when they are crushed or bruised, cut or chopped into small pieces or allowed to stand for long periods at room temperature both before and after cooking. Vitamin C losses can be decreased by refrigerating the vegetable until ready to prepare and serve, by using boiling water to start the cooking process and by using as small an amount of water in cooking as possible. The same methods which help to conserve the vitamin C value will also conserve riboflavin, thiamine and mineral values. All these food components are more or less water soluble.

Most of the green leafy vegetables are excellent sources of riboflavin, the leaves being much richer than the stems. A serving of cooked turnip or beet greens will supply nearly 25 per cent of the adult daily allowance. Spinach, kale, broccoli and collards supply about half as much, on the average. Headed cabbage and lettuce rank at the bottom of the list. Although the leafy vegetables contain several times the amount of thiamine required to metabolize their digestible calories, none of them can be ranked as rich sources of this vitamin. A serving of the better ones in this respect should supply on the average about one-tenth the day's allowance. The destruction in cooking usually does not exceed 10 to 15 per cent, but the addition of soda increases destruction, and when large amounts of water are used and discarded, large additional losses occur by solution. Certain leafy vegetables have been found effective in preventing and curing pellagra, but there are practically no data available regarding their specific nicotinic acid content.

In the amounts commonly consumed, leafy vegetables are of little significance as energy foods, but their higher carbohydrate content provides roughage, which is needed in certain diets. They are relatively richer in protein than in calories, and their protein ranks above seed proteins in general in biologic value. However, the actual contribution to the diet in the amounts commonly consumed is small.

Miscellaneous Vegetables—There are several other vegetables which, although limited as to general use, make important contributions to the diet of certain groups. The Hubbard, or winter, variety of yellow squash contains 6,000 international units of vitamin A per hundred grams. One-half cup of the cooked product supplies nearly one-half the adult daily allowance. Summer squash contains much less. Pumpkin furnishes approximately two-thirds as much as winter squash.

A serving of fresh asparagus (nonbleached) can furnish approximately one-fifth the day's allowance of vitamin A and one-sixth that of vitamin C. It is also a significant source of calcium and iron. Brussels sprouts are rich sources of vitamin C and also furnish significant amounts of iron, calcium and vitamin A. Cauliflower is notable for its content of ascorbic acid, thiamine and riboflavin.

One medium sized sweet pepper will furnish 460 international units of vitamin A and 180 to 200 mg of vitamin C. Chili peppers, whether fresh or dried, are a good source of vitamin A. Fresh chili is an excel-

lent source of vitamin C. Some of the vitamin C is retained on canning. Okra contains 2,380 international units of vitamin A per hundred grams. Parsley, which is used mainly for decoration, is an excellent source of both vitamin A and iron. When fresh it furnishes some vitamin C.

FRUITS

According to United States Department of Agriculture statistics for 1939, the present per capita consumption of fruits calculated on the fresh basis, was 221 pounds (100 Kg.). Of this total, 75 per cent was consumed fresh and 15 per cent canned, and the remainder was divided between dried fruits and juices. Apples outranked all other fruits, representing over one-fourth the total consumption. But citrus fruits as a class exceeded apples by 50 per cent or more. The nutritive values of various fruits have been excellently summarized in a recent article by Morgan,²⁴ and I have drawn on this article for many of the data which follow.

Fruits do not contribute important amounts of either calories or proteins to the diet, but they are of outstanding value because of their content of certain vitamins and minerals. As a class, fruits are important sources of ascorbic acid, certain members of the B complex, vitamin A, iron and other minerals, but there is a large variation among the different kinds as regards the extent of their contributions.

The citrus fruits are especially important for their ascorbic acid content. A medium-sized orange weighing around 5½ ounces (155 Gm.) will meet the daily adult allowance. A somewhat greater weight of grapefruit is required. Four and one-half ounces (130 Gm.) of canned orange or lemon juice or 6 ounces (170 Gm.) of canned grapefruit juice would supply the daily allowance. While the citrus fruits cannot be considered important sources of other nutrients, they do contain iron, calcium and thiamine in amounts which are of some significance in the diet. Pineapples, which are consumed mostly canned or as juice, contain about half as much vitamin C as do citrus fruits and are in general similar in other values.

Apricots and yellow peaches are important sources of vitamin A. The day's adult allowance is supplied by 3½ ounces (100 Gm.) of fresh or canned apricots or by approximately three times as much fresh or canned peaches. Weight for weight dried peaches and dried apricots supply approximately three times as much vitamin A as the fresh products. Canteloupes contain about half as much of this vitamin as do fresh peaches, and they are an important source of ascorbic acid. Dried prunes furnish significant amounts of vitamin A, riboflavin and thiamine. Plums rank above other fresh fruits in thiamine content. Apricots, peaches and to a lesser extent prunes are significant sources of iron.

Apples cannot be considered a large source of any vitamin or mineral nutrient. In view of their large consumption, however, they do make a significant contribution of ascorbic acid to the diet. A medium sized apple weighing 6 ounces supplies on the average about one-sixth the day's allowance, but there are decided differences among varieties. The keeping qualities of apples make it possible for them to be marketed throughout the winter in latitudes where fresh growth sources of vitamins are unavailable or high in price. In rural areas in which they are produced, home stored apples undoubtedly make an important contribution of

²³ Gould, Stella, Tressler, D. K. and King, C. G. Vitamin C Content of Vegetables. V. Cabbage. Food Research 1: 427 (Sept-Oct) 1936.

²⁴ Morgan, A. F. A Nutritive Index of Fruits. Fruit Products J. 21: 75 (Nov) 1941.

ascorbic acid to the diet during the winter season, when the problem of getting adequate supplies of this vitamin is most difficult. Apples also contain a significant amount of iron. There is a 25 per cent loss of vitamin C in making applesauce. The loss is greater when apples are baked or made into pie.

Bananas are similar to apples in vitamin C value; they contain almost twice the iron. Bananas are a significant source of vitamin A.

SUGAR, SYRUPS AND MOLASSES

White sugar contributes only calories to the diet. It is clear that the present large consumption of sugar is disadvantageous in that it means a smaller consumption of nutritionally superior foods. Furthermore, there is evidence that sugar is a factor in tooth decay. Brown sugar, corn syrup, honey, maple syrup and maple sugar contain small amounts of calcium and iron. Molasses is an excellent source of both, $1\frac{1}{2}$ tablespoons furnishing approximately one-tenth the estimated daily adult allowance of calcium and one-fifth the estimated daily adult need of iron. Sorghum supplies a lesser amount of calcium and about an equal amount of iron. Table blend syrups contain a significant but lesser amount of iron.

VEGETABLE OILS

Cottonseed, corn, soybean, peanut and olive oils and in lesser amounts other vegetable oils are consumed as shortenings, salad oils and margarine. The oils as such are sources only of energy. Many oleomargarines are now fortified with 9,000 international units of vitamin A per pound; they also supply some vitamin D.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES OF WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Acting Secretary

ALUMINUM PHOSPHATE GEL—An aqueous suspension containing not less than 3.8 per cent nor more than 4.2 per cent of aluminum phosphate (AlPO_4). Flavoring, sweetening and preservatives may be added.

Actions and Uses—Aluminum phosphate gel has antacid, astringent and demulcent properties analogous to those of aluminum hydroxide gel but does not interfere with phosphate absorption. Because the acid combining power of aluminum phosphate gel is less than one-half that of aluminum hydroxide gel of the same concentration, claims that it possesses advantages over the latter preparation in the treatment of peptic ulcer are not permissible except when the ulcer is associated with a relative or absolute deficiency of pancreatic juice, diarrhea or low phosphorus diet. The evidence indicates that, despite its lower combining power, aluminum phosphate gel therapy gives as good results in the treatment of peptic ulcer, but for the present its use should be restricted to patients under conditions or with complications likely to produce phosphorus deficiency.

Dosage—Fifteen to 30 cc (1 to 2 tablespoons) alone or with water or milk may be administered every two hours during the active stage of the ulcer. Later the dose may be reduced to 45 cc (3 tablespoons) four times daily (with or after each meal and at bedtime) or to 30 cc (2 tablespoons) six times daily (with or after and between meals and at bedtime).

Tests and Standards—

Aluminum phosphate gel occurs as a white odorless suspension which may settle out to some extent on standing. Its specific gravity at 25°C is from 1.032 to 1.044. The pH at 25°C of aluminum phosphate gel is between 6.0 and 7.2.

Dilute 1 Gm of aluminum phosphate gel to 100 cc and mix. To 5 cc of the diluted gel add 1 cc of sodium hydroxide solution 1 cc

of 1 per cent alcoholic alizarin sulfonate solution and neutralize with 36 per cent acetic acid; a flocculent red precipitate appears. To another 5 cc portion of the diluted gel add 2 cc of dilute nitric acid and 2 cc of ammonium molybdate solution; a yellow precipitate appears which dissolves in sodium hydroxide solution to yield a colorless solution. Add 30 cc of tenth normal hydrochloric acid to 6 Gm of aluminum phosphate gel and digest at 37°C for fifteen minutes; the pH of the mixture lies between 2.0 and 2.5.

Transfer 5 Gm of aluminum phosphate gel to a glass container, add 10 cc of diluted hydrochloric acid and agitate; the mixture yields a clear and colorless solution within ten minutes; to this solution add 8 cc of ammonia water; a flocculent precipitate appears which is insoluble in excess ammonia water but soluble in sodium hydroxide solution.

Dissolve 10 Gm of aluminum phosphate gel in 10 cc of diluted hydrochloric acid and boil. Cool, dilute to 250 cc and filter if necessary. To 10 cc add 1 cc of barium chloride solution and allow to stand for ten minutes; the turbidity is not greater than that produced by 0.2 cc of fifth normal sulfuric acid in 10 cc of water. Dissolve 2.5 Gm of the gel in 5 cc of diluted sulfuric acid and boil; the solution meets the U.S.P. test for arsenic. Dissolve 10 Gm of aluminum phosphate gel in 10 cc of diluted sulfuric acid; the resultant solution conforms to the U.S.P. test for heavy metals.

Transfer 25 cc of aluminum phosphate gel to a beaker, add 5 cc of nitric acid, 50 cc of distilled water and 40 cc of tenth normal silver nitrate solution. Mix thoroughly, digest, filter and wash the precipitate and titrate the filtrate with tenth normal ammonium thiocyanate solution using ferric ammonium sulfate as indicator; the chloride content does not exceed 0.15 per cent. Filter sufficient gel to yield 100 cc of filtrate. To 50 cc of the filtrate in a 250 cc beaker add 2 cc of nitric acid and 20 cc of ammonium molybdate solution. Digest on the steam bath for one hour, filter and wash the precipitate with 2 per cent nitric acid followed by washing with 1 per cent potassium nitrate solution until the filtrate is no longer acid. Dissolve the precipitate in excess tenth normal sodium hydroxide solution and titrate the excess alkali with tenth normal hydrochloric acid using phenolphthalein. Each cubic centimeter of tenth normal sodium hydroxide is equivalent to 0.309 mg P_2O_5 . The soluble phosphate calculated as P_2O_5 is not greater than 0.05 per cent. To a portion of aluminum phosphate gel weighing about 0.3 Gm accurately weighed, add a drop of 2 per cent alcoholic thymol blue, 30 cc of tenth normal hydrochloric acid and digest at 37°C for thirty minutes. Titrate with tenth normal sodium hydroxide and compare with an indicator solution adjusted to pH 2.5. Each gram of the gel requires no less than 5 nor more than 9 cc of tenth normal hydrochloric acid. Transfer about 20 Gm of aluminum phosphate gel accurately weighed to a 100 cc volumetric flask, add nitric acid until solution is complete and dilute to the mark. Mix thoroughly, transfer 10 cc to a 400 cc beaker, dilute to 100 cc, warm to 80°C, add an excess of ammonium molybdate solution and digest on the steam bath for one hour. Filter and wash the precipitate with 2 per cent nitric acid followed by 1 per cent potassium nitrate solution until the filtrate is no longer acid. Dissolve the precipitate in one-half normal sodium hydroxide and titrate with one-half normal acid using phenolphthalein as the indicator. Each cubic centimeter of one-half normal sodium hydroxide is equivalent to 2.654 mg of AlPO_4 . The calculated aluminum phosphate content is no less than 3.8 nor more than 4.2 per cent.

JOHN W. WETH & BROTHER, INC., PHILADELPHIA

Phosphaljel 12 fluidounce bottle. Aluminum phosphate gel containing 4 per cent of aluminum phosphate, 5 per cent of glycerin, not more than 0.5 per cent of sodium benzoate as a preservative and oil of peppermint as a flavoring agent.

Council on Foods and Nutrition

ACCEPTED FOODS

THE FOLLOWING ADDITIONAL FOODS HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO ACCEPTED FOODS.

FRANKLIN C. BING, Secretary

FRUIT JUICES INCLUDING TOMATO JUICE (See Accepted Foods, 1939, p. 48)

National Fruit Product Company, Winchester, Va.

WHITE HOUSE APPLE JUICE, a pasteurized sweet apple juice. **Analysis** (submitted by manufacturer)—Moisture 86.6%, total solids 13.4%, ash 0.3%, fat 0.25%, protein 0.3%, invert sugars 10.5%, sucrose 1.2%, acid 0.35%. Analytic data furnished by the firm show that the copper, arsenic and lead content of this product are well within the tolerances for these substances adopted by the Council. **Calories**—0.5 per gram, 14 per ounce.

PREPARATIONS USED IN THE FEEDING OF INFANTS (See Accepted Foods, 1939, p. 156)

Gerber Products Co., Fremont, Mich.

GERBER'S STRAINED PEACHES, canned cooked Michigan peaches, sugar and water.

Analysis (submitted by manufacturer)—Moisture 79.8%, protein (N \times 6.25) 0.6%, fat 0.9%, crude fiber 0.9%, ash 0.3%, carbohydrates (other than crude fiber) by difference 17.5%, calcium as Ca 0.007%, phosphorus as P 0.015%, iron as Fe 0.0005%.

Calories—0.8 per gram, 22.86 per ounce.

Vitamin—Vitamin A 1,020 U.S.P. units per hundred grams; thiamine 0.1 mg per hundred grams; ascorbic acid 2.8 mg per hundred grams.

SATURDAY, OCTOBER 31, 1942

FATIGUE AND WORKING CONDITIONS

Mechanization, speeding of industrial processes and mass production as a part of the war effort have combined to present new problems of industrial health. The illnesses of the workers, their accident rates and then industrial output have been shown to be closely related to fatigue. Physical fatigue, according to Sayers,¹ who reviewed this subject recently in *War Medicine*, may be temporary, subacute or chronic. Temporary fatigue is a normal feeling of tiredness that passes away after a short rest and allows resumption of original work without decrease in efficiency. Subacute fatigue may result from continued activity at the same intensity until energy reserves are depleted. This condition, if unchecked, may become chronic. Chronic fatigue, the final stage of a series of events which begins with overwork, may end in disabling illness. Fatigue may be local or general. Local fatigue affects particularly the muscles that have been employed most actively. General fatigue affects the whole body and frequently results from such conditions of work as excessive hours, curtailed periods of rest and insanitary, uncomfortable or hazardous surroundings. Any type of chronic fatigue may affect the health or liability to accidents of workers and consequently volume or quality of plant output as well.

Accurate knowledge of optimum working conditions is therefore important to the health of workers and ultimately to the production problem. Obviously the circumstances leading to fatigue and the methods of preventing fatigue will vary from industry to industry and will depend on the type of activity actually carried out by the individual worker. There will also be variation between what a worker can do safely for short periods of time as contrasted with prolonged effort. Nevertheless there are certain general principles,

reviewed by Sayers, which are applicable to practically all industries. A final answer cannot be given to the question "What is the optimum number of hours of work?" Within limitations, reduction in hours of work leads to a decrease in accidents, spoiled work, sickness and absenteeism. Likewise there is such an increase in hourly output that daily output also increases. In one large factory where weekly hours were first 74.5, then 63.5 and later 55.5, speed of production increased after each reduction. Similar observations have been made elsewhere. In an American munitions plant the hourly output fell by 65 per cent when 2.66 hours of overtime was added to the normal ten hour day. Sayers cites Knight, who concluded that the reduction of working hours from twelve to ten leads to an increase in hourly and daily output, the reduction of working hours from ten to eight leads to a further increase in hourly and daily output, except in operations whose speed depends mainly on the speed of machines. Finally reduction of working hours below eight, although increasing hourly output, does not usually lead to an increase in daily output.

The published experience in both Germany and Great Britain, where hours of labor were generally increased during the early phases of the war, indicate that ten hours a day is the maximum number which can be worked with reasonable efficiency. In a speech to the House of Commons on July 29, 1941 Prime Minister Churchill summarized this view when he said "It we are to win this war it will be largely by staying power. For that purpose there must be one day in seven for rest as a general rule and there must be one week's holiday a year."

The experience of Jokl, Chiver and their colleagues of South Africa in training recruits who were substandard mentally and physically, cited by Sayers, is also applicable to this problem. From 1932 to 1939 nearly fourteen thousand boys between the ages of 16 and 21 who were unable to find employment were recruited for physical training. After first finding the physical training strenuous they changed their attitude and came to like the exercise, their physical efficiency and resistance to fatigue were remarkably improved. This may be considered as corroborative of the well known fact that physical training for any particular activity increases the ease with which that activity is done and decreases the likelihood of fatigue. Physical training may reduce liability to fatigue to such an extent that hours of work can actually be increased with safety.

The information already available on this subject, when applied to individual industries and whenever possible to individual procedures within those industries should be used to attain maximum output without resultant fatigue to the workers.

RECENT TRIBUTES TO PHYSICIANS

Three notable tributes have been paid recently to the services of the medical profession in time of war. One of these was by a Washington columnist, another by a well known radio commentator and the third by a famous newspaper cartoonist.

In his column "In the Capital" Ernest Lindley,¹ discussing manpower control, cited the medical profession as an example of the trial of voluntary allocations before proceeding to compulsory methods. Mr Lindley tells how the medical profession has succeeded in supplying doctors to the armed forces.

Supplying the armed services with medical officers has provided an interesting test. A few months ago the prospective shortage of physicians in the Army was serious. The job of overcoming this was undertaken by the War Manpower Commission with the cooperation of the American Medical Association and its state and local affiliates. A roster of 176,000 licensed physicians was available from which to draw the military quota of 42,000 for 1942, while preserving as far as possible an even distribution of medical care for the civilian population.

This recruitment is still in process. With the year almost three fourths gone, five sixths of the quota has been filled. State and local medical groups have stood watch against dangerous depletion, and, on the whole the authorities report an overall balance of medical care has been preserved.

Recently, however, a survey showed that 300 war boom towns lack adequate medical staffs. The American Medical Association approved experiment with three alternative plans for supplying this need: payment of moving expenses to volunteer doctors; federal salaries to supplement their fees; and the temporary commissioning of doctors in the Public Health Service.

Deems Taylor,² well known musical and radio commentator, paid a tribute to the medical profession over the Columbia Broadcasting System on Sunday, September 20. The following are excerpts from Mr Taylor's broadcast, minus the music and dramatic presentation which greatly enhanced its effectiveness.

We come now to that special feature of the Prudential Family Hour "So Proudly We Hail," in which we pay tribute to the men, the nations and the services that are in the forefront of our fight for freedom. Today So Proudly We Hail the United States Army Medical Corps.

Yes, the medical men are here and ready—they were at Pearl Harbor. And we know now of the wonderful work they did in caring for the wounded. They were there as they have always been in every national emergency. As they were in 1775 when the Medical Corps was first organized. It was during the siege of Boston that the Second Provincial Congress passed an act providing two surgeons and two surgeons' mates to a hospital. In the lull between the battles of our first fight for freedom the men of the Continental Army wondered about the

new act. "What'll the doctors do? What are their duties?"

Well the act of Congress says that the doctors must see that our wounded have plenty of fresh clean straw to lie on.

There was little more than that expected from our first medical corps but the men of medicine had ideas of their own. From this humble beginning they've built the greatest medical service in the world. Today they maintain a chain of top notch military hospitals costing well over a hundred and sixty-five million dollars. It was an American surgeon Jonathan Letterman who during the Civil War devised the method for evacuating field casualties that has become the basic pattern of all big warring powers today. Through their skill and devotion the medical men of 1942 have created the healthiest army in the entire world. They have brought their talents to the Colors from every town and hamlet in the land. They are the men whose prescriptions

were filled in corner drug stores. They are the men who from the sickrooms of America heard the call of American wounded in far off places. They are men like—well say Dr Thomas Thurston of a little town in the Midwest.

Here followed an interlude of drama between Dr Thurston and little Mary, his patient who insists she doesn't want any other doctor but who finally is persuaded that his duty lies to many other patients who wear the uniform of the United States armed forces.

Dr Thurston is Lieutenant Thurston of the United States Army Medical Corps now. Like thousands of his brother physicians he heard and answered the call. A cherished career and the practice built through many trying years set aside, with never a thought of anything but the service that lies ahead. Maybe little Mary will have her Dr Thurston again. Maybe not. For physicians die in battle too. They die so that others

UNSUNG HEROES

Cartoon by Vaughn Shoemaker reproduced from the Chicago Daily News of October 10

¹ Chicago Sun, September 24, p. 11
² The Family Hour, Prudential Insurance Company of America, Station WABC 5:45 p. m., September 20

may live. It's a long way from the bedside of a little girl in the Middle West to a battle salient somewhere on Bataan. Yet the men who carried their little black medical bags into houses on Main streets were the same men who carried the comfort of the Medical Corps to the fox holes where our liberties were first challenged.

The cartoon by Vaughn Shoemaker of the Chicago *Daily News*, which appeared Saturday, October 10, showed a bearded old fashioned doctor, too old for service, in his office beyond a waiting room filled with patients. The cartoon speaks for itself, telling better than many paragraphs the burdens now resting on America's family doctors.

Current Comment

HEALTH NEWS BROADCASTS BY PROVIDENCE MEDICAL ASSOCIATION

"Health in the News"¹ is the title of an interesting series of news broadcasts presented between Oct. 31, 1941 and July 29, 1942 over radio station WEAN, Providence, R. I. Prepared and presented by its executive secretary, the broadcasts were made under the auspices of the Providence Medical Association. They have been broadcast at various times of day including choice evening hours between 7 and 9 o'clock Fridays. These broadcasts are notable for the wide range of their topics. In one broadcast, for example, is the story of the discovery of Ras Nefer, the oldest Egyptian mummy in the world, followed immediately by an item headed "School Days for Your Doctor" and descriptive of the Boston meeting of the American College of Surgeons plus a reference to the forthcoming scientific meeting of the Providence Medical Association. This is followed by a sports item dealing with Fred Hutchinson and Bob Feller, baseball pitchers now enlisted in the United States armed forces. The tie-up with medicine was the fact that Hutchinson is the son of a Seattle obstetrician and that a cast of Bob Feller's hand by sculptor Joseph Motto is a part of the exhibit of men's hands in the Cleveland Museum of Health. Immediately following this is a historical reference to René Laennec, this is associated with the use of stethoscopes to diagnose whether Nazi delayed action bombs remain alive or dead. In the same news broadcast is a postage stamp collectors' item having to do with efforts to issue a United States postage cancer control stamp. Then appears a reference to Mother Hubbard, intimating that in Bay City, Mich., she can no longer go to the grocery store with her dog because of a new sanitary ordinance. News of strikes and walkouts includes a story of one which was responsible for canceling the meeting of the Pennsylvania State Medical Society, thus depriving doctors of some valuable scientific opportunities. The broadcast closed with a reference to a *Hygeia* article on why babies smile, this item closed on the semihumorous personal note "I shall continue to delude myself that my Linda Ann really thought my antics worth her smile in the first weeks at our home." This radio program,

of which the first broadcast has been described in detail, holds up remarkably well through the long series of weekly broadcasts from October through July with items covering the whole gamut of human interest, world news, tragedy, whimsy and every phase of listener appeal. It bears the evidence of long hours spent in conscientious labor, without which no radio broadcast or other effort in health education could succeed. The fact that a radio station continued to broadcast it regularly during the premium evening hours for which commercial sponsors compete is in itself evidence that it was a distinctly worthwhile program for all persons concerned, especially in wartime. It was good for the medical society because it interpreted Rhode Island physicians to the people. It was good for the radio station because it provided them with a popular educational public service feature. It was good for the public because it gave them helpful information, medical news and a better understanding of their doctors.

THE PHYSICIAN'S PART IN THE RATIONING OF GASOLINE, TIRES AND FUEL OIL

Under Medicine and the War in this issue of *THE JOURNAL* appears a letter to physicians of the United States from the chief of the Gasoline Rationing Branch of the Office of Price Administration. It calls on the medical profession not only to comply fully with the actual stipulations relative to the rationing of gasoline and tires but also to go beyond such limitations into the spirit of the effort which is so intimately concerned with the winning of the war. Doctors should adhere religiously to the provisions of the regulations and should set an example to all other persons in the community by the economy with which they use these materials. When Mr. John R. Richards says that doctors are the leaders and molders of public opinion in their communities, he recognizes the dependence of the public on medical leadership in all matters concerned with health. Already such recognition has come from the director of the Fuel Rationing Division. Physicians are authorized to certify invalids, old people and infants for extra fuel oil. Mr. Joel Dean, director of this division, points out that the rationing boards will naturally rely largely on physicians' certification. He says "If these auxiliary rations are granted with unjustified liberality, the effectiveness of the entire effort to distribute this scarce commodity equitably and to assure continuance of oil for industrial processes in war plants will be jeopardized. I am sure that the medical profession, when it realizes the seriousness of this additional responsibility, will discharge it conscientiously and patriotically." The patriotism of the medical profession has never been questioned. In this great war physicians have demonstrated their support by their magnificent enlistment in the armed forces and by assuming innumerable obligations in relationship to the control of civilian life. Let us, by the manner in which we aid in the programs for the rationing of fuel, gasoline and tires, demonstrate again to the people of America that confidence in and dependence on the medical profession is well warranted.

¹ Health in the News prepared and presented by John E. Farrell, Executive Secretary, Providence Medical Association, Providence, R. I. over radio station WEAN (Providence) Oct. 31, 1941; July 29, 1942.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

GASOLINE AND TIRE RATIONING

AN OPEN LETTER TO THE MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

In the East Coast Gasoline Rationing program, made necessary by the shortage of transportation facilities for petroleum products, the indispensability of your profession was recognized by its inclusion in the categories of persons eligible for preferred mileage, that is, necessary occupational mileage in excess of 470 miles a month. Now the Office of Price Administration has been ordered by Mr. William Jeffers to institute and administer a nationwide mileage rationing program for the express purpose of conserving our rubber-borne transportation. In framing the Regulations for the new program, your profession was one of the first to be provided for.

If we are to carry out our double task of preventing a collapse of our military and civilian transportation, we must have the complete cooperation of those groups of persons whose driving is deemed essential to the war effort. Our immediate aim is to attain the 5,000 mile national mileage average set by the Baruch Report as the maximum possible in light of the dire rubber shortage. Our experience with the East Coast program tells us that the preferred categories use one half of the gasoline consumed, though they constitute less than one fourth of the total number of automobile operators. Clearly, then, the great savings of rubber on a nationwide scale must be made in the preferred categories.

Under the Regulations, governing the mileage rationing program, physicians are eligible for preferred mileage if their essential occupational needs exceed 470 miles a month and if the mileage is needed for regularly rendering necessary professional services. Mileage traveled daily or periodically between home or lodging and a fixed place of work is not considered preferred. Physicians who conduct their practices in offices, as many specialists do, are not eligible for preferred mileage.

Without question or hesitation, doctors have been and will be granted all the gasoline needed to carry out their professional work. We hope that they will regard their concrete symbol of their indispensability, the C book, as a moral obligation and not as a personal privilege. From another point of view, the C book is part of a doctor's equipment, it should not be used for anything but the work of humanity.

When nationwide gasoline rationing begins, there are certain concrete things a doctor can do to live up to the high ethical standards set for him by his own profession.

1 At the time of first issuance of rations, he can so carefully compute his necessary mileage as to make a B book adequate for his purposes though he might easily make out a case for a C book, which might be granted to him without question by his local War Price and Rationing Board eager to provide for physicians.

2 In the computation of his mileage, he can religiously adhere to the provision of the Regulations, which makes 150 miles of his basic ration available for occupational purposes. Moreover, he can help mightily in establishing the principles that only 90 miles of the basic ration are to be used for home neces-

sity use and that there is no provision whatever in any ration for "pleasure driving"

3 Conversely, if he should be granted a C book, he can return to the local board, at the end of the three months period, all unused coupons accruing to him as a result of a quite natural overestimation of needs or of overgenerous "tailoring" by his board, instead of using such coupons for nonessential purposes. The moral effect of such an act on his fellow citizens will be incalculable.

4 He can set an example by scrupulously observing the 35 mile speed limit, except in cases of emergency, in spite of the fact that doctors could easily "get away with it."

5 Should he be assigned to a hospital, clinic or institution after a ration card for calling on his private practice has been issued, he can use public means of transportation at the price of personal inconvenience.

6 He can refrain from any kind of driving whatever which might appear to be nonessential in the eyes of the public.

Doctors are the leaders and molders of public opinion in their communities. If the average man has any reason to believe that the professional men whom he regards with great respect are indifferent or hostile to the mileage rationing program, it will be difficult, if not impossible, to make it effective. Conversely, if doctors as a group observe the letter and spirit of the Regulations, they will be a powerful force in making this absolutely mandatory war measure serve its purpose. We know that we can rely on the support of your profession, which has demonstrated its patriotism, ability and unselfishness at every opportunity.

JOHN R. RICHARDS, Chief Gasoline Rationing Branch, Office of Price Administration

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

1942 OBJECTIVE IN PROCUREMENT OF MEDICAL OFFICERS ALMOST REACHED

The directing board of the Procurement and Assignment Service is pleased to announce that 95 per cent of the 1942 procurement objective of medical officers for the armed forces has already been met. Toward this total a number of states have supplied more than their share of physicians and only a few states are lagging behind in their quotas. It is from these states that the additional physicians needed during the current year should come.

The recruitment of such a large number of physicians in a few months is a remarkable achievement and another demonstration of the traditional patriotism and unselfishness of the medical profession. In this achievement, and particularly in its members who are "in service," the profession can justifiably take pride.

The end, of course, is not yet. Increases in the armed forces will necessitate more medical officers, and additional demands will be made on the profession for medical services in critical war production areas. The directing board is convinced, however, that the physicians of this country will respond to future calls for service, whatever they may be, in the same splendid manner with which they have already volunteered for service with the armed forces.

MEDICAL EDUCATION AND THE WAR

The following statement from the directing board of the Procurement and Assignment Service, Washington, D. C., has just been sent to the deans of medical schools:

MEDICAL STUDENTS

Recent information indicates that a relatively large percentage of medical students have failed to join the reserve services of the Army or the Navy. It is urged that every student who has not yet done so should apply immediately for a commission in the Army or the Navy. This will enable medical students to continue their training through one year of internship before they are subject to Selective Service.

INTERNS

Army—Interns may not enlist in the Medical Administrative Corps Reserve since this group was organized solely for the purpose of enabling medical students to complete their training. If a student is not a member of the Medical Administrative Corps, he is subject to the jurisdiction of the Selective Service System and may be inducted before he can complete the one year of internship which is required for commission as first lieutenant in the Medical Corps of the Army of the United States. Interns whether or not they have been in the Medical Administrative Corps Reserve during their attendance at medical school cannot apply for a commission in the Army Medical Corps until sixty days before the completion of their internships.

Navy—The Navy will commission interns as lieutenants, junior grade, if they meet the requirements, and it will allow them to complete their internships. We recommend, therefore, that students who contemplate service in the Navy should apply for commissions as ensigns (P) in the Navy while they are in medical school.

FACULTIES

It is recommended that deans request faculty members who plan to apply for a commission to discuss the matter with school authorities before making formal application. A physician who

is deemed essential on the faculty of a medical school should not apply for a commission until he has been cleared by the school and by the Procurement and Assignment Service and until arrangements have been made for his replacement.

No physician under 45 years of age, who is physically fit for military service, should be declared essential to a medical school faculty unless he devotes at least 25 per cent of his time throughout the entire year to medical school teaching, clinical as well as formal. Any exception to this policy must be justified by unusual circumstances.

ALIEN PHYSICIANS

The following statement by the directing board of the Procurement and Assignment Service has just been sent to state chairmen for physicians:

The Army and the Navy are not in a position to accept enemy alien physicians as commissioned officers because of the citizenship law. Also many of these physicians do not meet other requirements such as license to practice, internship or other professional qualifications. It therefore seems inadvisable to recommend that these aliens go into the Army as privates with the expectation of receiving citizenship at the end of three months, for many may not receive it for some reason, and they may not be acceptable to the Medical Corps even though they are given citizenship. Since there are many places in which these men can be of service in civilian life, it is recommended that efforts be made to place those who are not acceptable for service with the Army or the Navy as temporary employees in hospital positions, in critical areas where more physicians are needed, in special positions in medical schools, and in public health agencies and so on. In such positions they may be rated as essential and may thus be used in their professional capacity. Until definite rulings are made concerning the admission of this group into the military services, these general policies should be followed.

ARMY

STATUS OF MEDICAL STUDENTS AND INTERNS WITH MEDICAL CORPS OF THE ARMY

THE JOURNAL on August 15 published an article by Major Gen James C Magee, the Surgeon General, U S Army, concerning medical education and the war. The last two paragraphs briefly detailed the provisions which were then in existence to permit medical students to continue their training by granting deferment from the draft. A modification of the announced policy necessitates a revision of that portion of General Magee's article.

The policy now in effect provides "that appointments in the Medical Corps of officers could be made only when an applicant is fully qualified in accordance with standards prescribed by the Surgeon General and approved by the War Department, and when their services are immediately available to the War Department in compliance with paragraph 7, AR 605-10."

This change, in particular, alters the status of interns and the manner and time in which they may be commissioned in the Medical Corps of the Army of the United States. In brief it is now provided that instead of commissioning interns at the time of graduation as First Lieutenants, Medical Corps, Army of the United States, they will continue their R O T C line commissions (Infantry, Field Artillery, Cavalry and so on) throughout their four years of medical school and one year of essential rotating general internship. Then within sixty days of the time they are expected to complete the internship and go on active duty they may apply directly through the headquarters of the service commands, local medical officer recruiting boards or to the Surgeon General's Office for commissions in the Medical Corps, Army of the United States. This action was made necessary by the administrative difficulties of appoint-

THE COMMISSIONING OF VETERINARIANS

The directing board of the Procurement and Assignment Service, Washington, D C, recently requested information from the Surgeon General's Office about its policy concerning the commissioning of doctors of veterinary medicine. It seemed to the board that valuable veterinary manpower was being lost through the induction of veterinarians as enlisted men and their subsequent commissioning through routine military channels.

The board asked the Surgeon General's Office if it would not be possible for veterinarians to apply for commissions on receiving their orders for induction. In reply, the Surgeon General's Office gave the following information:

1 Routine commissioning of additional veterinarians in the Veterinary Corps was suspended two years ago.

2 Veterinarians now commissioned are in excess of the current needs and the needs of the immediate future.

3 The conserving of veterinary manpower should be considered a function of Selective Service.

4 If considerable numbers of veterinarians are inducted as privates, the War Department will not be able to commission them immediately because of lack of position vacancies.

The directing board therefore recommended on October 12 that all state veterinary chairmen immediately prepare surveys of the veterinary manpower and its distribution for their respective states in order that the need for the occupational deferment of veterinarians might be factually substantiated in requests to the local Selective Service boards for the deferment of veterinarians. The data included in these surveys should be sufficient to enable these boards to judge the essential character of the work of any veterinarian for whom deferment is sought on the ground of occupational essentiality. It is further suggested that state chairmen immediately communicate with the state director of Selective Service for a discussion of the problem. It is apparent that deferment in the future will depend on the decision of the Selective Service boards.

ing such officers prior to their internships and not calling them to active duty until such internship was completed.

PROCUREMENT OF LOANS BY STUDENTS

A further matter of interest in this connection is that concerned with the procurement of loans by students. The following extract from Public Law 647, Seventy-Seventh Congress, Chapter 475, second session (H R 7181), is quoted:

"Loans to students in technical and professional fields (national defense). To assist students (in such numbers as the chairman of the War Manpower Commission shall determine) participating in accelerated programs in degree granting colleges and universities in engineering, physics, chemistry, medicine (including veterinary), dentistry and pharmacy whose technical or professional education can be completed within two years, as follows:

"Loans. For loans to students whose technical or professional education can be completed within two years to enable them to pursue college courses, who attain and continue to maintain satisfactory standards of scholarship, who are in need of assistance and who agree in writing to participate, until otherwise directed by said chairman, in accelerated programs of study, in any of the fields authorized hereunder, and who agree in writing to engage, for the duration of the wars in which the United States is now engaged, in such employment of service as may be assigned by officers or agencies designated by said chairman, such loans to be made by such colleges or universities or public or college connected agencies from funds paid to them on estimates submitted by them as to the amounts necessary therefor, \$5,000,000 provided that, in case it shall be found that any payment to any such college, university or public or college connected agency is in excess of the needs thereof for the purposes hereof, refund of such excess shall be made to the

Treasurer of the United States and the amount thereof credited to this appropriation. Loans hereunder shall be made in amounts not exceeding tuition and fees plus \$25 per month and not exceeding a total of \$500 to any one student during any twelve month period, said loans to be evidenced by notes executed by such students payable to the Treasurer of the United States at a rate of interest at 25 per cent per annum. Repayments of such loans shall be made through the colleges, universities or other agencies negotiating the loans and covered into the Treasury as miscellaneous receipts provided that indebtedness of students who, before completing their courses, are ordered into military service during the present wars under the Selective Training and Service Act of 1940, as amended, or who suffer total and permanent disability or death, shall be canceled. The foregoing loan program shall be administered in accordance with regulations promulgated by the Commissioner of Education with the approval of the chairman of the War Manpower Commission."

ST MARY'S HOSPITAL UNIT

The first U S Army Station Hospital to be organized in West Virginia began training at Fort McPherson, Atlanta, Ga., October 1. This unit, to be known as the St Mary's Hospital Unit was organized by Lieut Col Charles Frederick Fisher of Clarksburg, who will be in command of the unit, comprising eighteen doctors, forty-three nurses and about eighty-five hospital corps men, technicians and other members to be assigned by the Surgeon General's Office. Seven of the physicians in the unit were members of the staff of St Mary's Hospital and ten of the nurses are graduates of the nursing school. The other members came from Wheeling, Fairmont, Lumberport, Parkersburg, Parsons and Weston. The unit was organized for service abroad. Wounded men in battle are evacuated to the station hospital in the field from the first aid dressing station, which is usually near the front lines. The station hospital may be set up at different points as the battle progresses. The St Mary's Station Hospital Unit will have a capacity of 250 beds but will have equipment to care for temporarily as many as a thousand wounded soldiers before being taken farther back, the next hospital toward the rear being the evacuation hospital. The physicians on the staff of the St Mary's Hospital, in addition to the officer in charge, will be Major Robert W. Lukens of Wheeling, chief of surgery, Major Robert H. Jones of Fairmont, chief of medicine, Capt William H. Allman of Clarksburg, assistant surgeon, Capt Edward Vacheresse Jr. of Fairmont, 1st Lieut Joseph Gilman of Clarksburg and 1st Lieut Wilson S. Phillips of Wheeling, ward surgeons, 1st Lieut Paul McCuskey of Clarksburg and Raymond B. Nutter Jr. of Lumberport, assistant ward surgeons, Capt Francis G. Gennin of Clarksburg, psychiatrist, Capt Karl L. van Horn of Fairmont, eye, ear, nose and throat, Capt Samuel Weisman of Parsons, radiology, Capt Robert T.

Humphries of Clarksburg, orthopedic surgery, and Capt. John McCuskey of Clarksburg, genitourinary surgery.

In addition to the members of this hospital unit, various other members of the medical staff of St Mary's Hospital and many graduates of its nursing school are already serving in the armed forces in various parts of the world.

WANT DOCTORS TRAINED IN SKIING AND MOUNTAIN CLIMBING

The Mountain Training Center, Camp Carson, Colo., reports that with the rapid expansion of the Mountain Troops the Army faces a shortage of medical officers with sking or mountaineering experience. The War Department wants doctors and dentists who have a basic knowledge of sking or mountain climbing. Mountain warfare is a specialized type of combat in which the treatment of injured men can best be handled by a medical unit skilled in the use of skis and climbing equipment. A wounded trooper's life may depend on the ability of his rescuers to ski to his aid.

Qualified doctors in or about to enter the military service are advised to make immediate application to the Adjutant General's Office, War Department, Washington, D. C., requesting assignment to the Mountain Troops.

MARRIED NURSES TO CONTINUE ON ACTIVE DUTY

The War Department announced that, effective October 1, members of the Army Nurse Corps who marry will, at the discretion of the Surgeon General, be continued in active service for the duration of the war and for six months thereafter. Heretofore nurses were discharged from the service on marriage. Nurses now on duty will not be permitted to resign unless replacements are available, and nurses appointed and ordered to active duty after Dec. 27, 1941 will not be permitted to resign during the present emergency. Those of the latter group will be released only for physical disability or incompetence.

ARMY ORDERS

Dr. Leo V. Schneider, Glenn Dale, Md., associate clinical professor of medicine at Georgetown University School of Medicine, Washington, D. C., has been ordered to active duty as a major and will be stationed at the Lawson General Hospital, Atlanta, Ga.—Lieut Col John P. Beeson, who has been in command of the station hospital at Fort Hancock, N. J., has been ordered to take command of the hospital at Salina, Kan. Colonel Beeson served in the last war in France as chief of the surgical staff of an evacuation hospital near Verdun. Major Nicholas R. Locascio, New York, formerly chief of the medical service at Fort Hancock, will succeed Colonel Beeson as commander of the station hospital there.

CIVILIAN DEFENSE

EMERGENCY BASE HOSPITALS

The Medical Division of the U S Office of Civilian Defense, through its regional medical officers and state chiefs of Emergency Medical Service, has now made emergency provision for the establishment of a chain of emergency base hospitals in the interior of all the coastal states. They will be activated only in the event of an enemy attack on our coast which necessitates the evacuation of coastal hospitals. Each base hospital will be related to the casualty receiving hospital which has been evacuated, and it is expected that the staff will be recruited largely from the parent institution.

In order to meet a sudden and unexpected crisis without delay, arrangements have been completed with state authorities for the prompt taking over of appropriate institutions in the interior of the state for this purpose and with local military establishments for the transportation of casualties and other hospitalized persons along appropriate lines of evacuation.

More than one hundred and fifty hospitals in the coastal cities are in the process of organizing small affiliated units of physi-

cians and surgeons, which will be prepared to staff the Emergency Base Hospitals if they should be needed. These units are composed of the older members of the staff and those with physical disabilities which render them ineligible for military service, and of women physicians. In order that a balanced professional team may be immediately available the doctors comprising units are being commissioned in the inactive reserve of the U S Public Health Service so that, if called to duty, they may receive the rank, pay and allowances equivalent to those of an officer in the armed forces. Dr. George Baehr, chief medical officer of the U S Office of Civilian Defense, states that the members of these affiliated hospital units will continue to remain on an inactive status for the duration of the war unless a serious enemy attack occurs in their region which necessitates the transfer of casualties to protected sites in the interior. Their commissions may be terminated on their request six months after the end of the war, or sooner if approved by the Surgeon General. Such approval will be given in the event such officer desires active duty in the Army or Navy.

MISCELLANEOUS

GENERAL LIMITATION ORDER ON X-RAY EQUIPMENT

The manufacture and purchase of x-ray equipment will be circumscribed under General Limitation Order L-206, issued by the War Production Board under date of October 20¹. Within the meaning of this order, x-ray equipment includes the following: radiographic equipment, fluoroscopic equipment and therapy equipment, power units, radiographic, fluoroscopic and therapy tables, photofluorographic units, cassette changers, tube stands, stationary grids, and Bucky diaphragms. The order does not apply to use of rebuilt equipment or to any parts, accessories or appliances used in connection with radiography, fluoroscopy or therapy other than the items specifically named.

The order provides that no manufacturer shall manufacture or assemble any models or types of x-ray equipment other than the permitted number of models or the types set forth and described in a schedule published concurrently with the order. No person may sell, transfer or deliver any x-ray equipment except:

"(i) To the Army or Navy of the United States, the United States Maritime Commission and the War Shipping Administration, or

"(ii) To persons (such as hospitals, medical departments of industrial concerns, and other persons desiring to receive x-ray equipment) who have filed Form PD 556 and have been specifically authorized on such form by the Director General for Operations to receive x-ray equipment."

Each person seeking authorization to receive x-ray equipment must prepare Form PD-556, copies of which may be obtained at the local offices of the War Production Board in the manner prescribed in the form. The form should be filed only by the person desiring to receive x-ray equipment and not by the person who makes delivery of such equipment. The application must state whether or not the applicant has in use any x-ray equipment as defined in the order and if so must give a description of it, must state the average number of patients per week on which such equipment is used and whether the equipment applied for would be used to replace existing equipment or is needed for expansion of existing facilities. The order form must show how the applicant accomplishes the work for which the equipment applied for would be used and must indicate what attempts have been made to obtain used or rebuilt equipment.

Any person affected by the order who considers that compliance therewith will work an exceptional and unreasonable hardship on him may apply to the War Production Board setting forth the pertinent facts and the reasons such person considers that he is entitled to relief. The Director General for Operations may thereupon take such action as he deems appropriate. The order and all transactions affected thereby are subject to all applicable provisions of the Priorities Regulations of the War Production Board.

WAR RECREATION CONGRESS

More than nine hundred delegates from the United States, Canada and England attended the War Recreation Congress in Cincinnati, September 28-October 2 (*THE JOURNAL*, August 8, p. 1207). All branches of the armed forces, many other agencies of the government, representatives of industry and organized labor and delegates from both public and private agencies participated in the eight general sessions, thirty-six discussion meetings and many special meetings and luncheons. The full proceedings of the conference are being printed and will be available soon.

The director of the Division of Recreation of the Federal Security Agency, Mr. Mark McCloskey, discussed the recreation services for men in uniform and workers in industry in communities throughout the country and in certain overseas bases. Lieut. Comdr. Arthur T. Noren of the U. S. Navy and Colonel Dumont of the Special Service Division of the Army told of the recreational programs being carried on directly in the camps by the Army and Navy. Mr. Harry Wann outlined the recreation services being performed by the American Red Cross within base hospitals and in clubs overseas. Mr. Ray Johns of the United Services Organization told of the special

services performed by this organization in providing clubs and other recreational services in various communities. One general session was devoted to recreational services for industrial workers. Special attention was given to wartime problems of girls and women. It was said that one of every five boys has an opportunity for favorable recreational activities, while only one of ten girls has this opportunity. The release from the National Recreation Association states that a spectacular increase in juvenile delinquency, especially among girls from 12 to 15 years of age, has occurred since the United States entered the war. It was announced that thirteen million women are now engaged in war industry with five million more expected by the end of the year. Communities were urged to see that recreation agencies were cooperating in providing recreation facilities and leadership to serve these women. Among other problems before the War Recreation Congress were home and family recreation, recreation provided by churches, boys' and girls' clubs, organized camping and the use of music and drama in recreation programs.

Concern was expressed by the leaders of the recreation movement over the question of personnel. They are faced with demands for greatly increased service and at the same time with the loss of trained personnel. Many cities already have lost their chief executives in the field of recreation.

MENTAL HYGIENE OF WAR SERVICE FOR EIGHTEEN AND NINETEEN YEAR OLD MEN

AN OPEN LETTER

So much has been said and so much implied about the desirability of drafting 18 and 19 year old men for military service from the point of view of emotional stability that it seems that, in the public interests, a simple, direct statement should be made on this question.

Speaking as individuals, we wish to assure the public and parents of this age group that there are no grounds for apprehension as to the effect of military service on these younger men as distinguished from the older men. Such statistics as are available indicate that the incidence of mental breakdowns is no greater in the 18 and 19 year age group than in the older group. If anything it is somewhat less. It would seem to us that the proposal now before the American Congress does not unduly compromise the future mental integrity of this particular age group or of the nation. With the government realizing and properly assuming this increased responsibility, we endorse favorable action on the proposal to include men of 18 and 19 years under the Selective Service Act.

ORGANIZATION SECTION

OFFICIAL NOTES

ANNUAL CONFERENCE OF SECRETARIES AND EDITORS

The Annual Conference of Secretaries and Editors of Constituent State Medical Associations will be held at the offices of the Association in Chicago on Friday and Saturday, November 20 and 21.

The first meeting will begin at 10 a. m., Friday, November 20. An afternoon meeting and an evening meeting will be held on November 20 and the conference will adjourn at the end of a morning meeting on Saturday, November 21.

The program has been arranged in accord with the expressed wishes of state secretaries and editors who have indicated the nature of subjects which they wish to have discussed. The Surgeon General of the United States Navy and the Surgeon General of the United States Public Health Service will address the conference at the first meeting on Friday morning, November 20. The Surgeon General of the Army has expressed regret that it will not be possible for him to be present, but he will be represented by Brig. Gen. L. B. McVee, who is well known to many of the members of the conference. The chairman of the directing board of the Procurement and Assignment Service, Dr. Frank H. Lahey, Past President of the American Medical Association, and Dr. L. G. Rowntree, representing the Selective Service System, will also address the conference during its first day, as will Dr. Creighton Barker of Connecticut who has made some intensive studies pertaining to the provision of medical care of the civilian population in crowded areas. Dr. Walter F.

Donaldson, chairman of the War Participation Committee of the American Medical Association, will present a paper.

The first meeting of the conference will be called to order by Dr. Roger I. Lee, Chairman of the Board of Trustees of the American Medical Association, at 10 a. m., Friday, November 20. After the selection of a chairman, Col. Fred W. Rankin, President of the American Medical Association, will address the conference and at the opening of the afternoon meeting, on Friday, November 20, Dr. James C. Paullin, President Elect of the American Medical Association, will present an address. A dinner meeting will be held on Friday evening, November 20, at which Dr. Stanley B. Weld, editor of the *Connecticut State Medical Journal*, will preside and will deliver an address. Dr. Julian P. Price of South Carolina will present a paper which will deal with the best methods of disseminating information among the members of county and state medical societies.

At the meeting of the conference Saturday morning, November 21, Dr. James C. McCann of Massachusetts will discuss the general subject of medical service plans and Mr. A. M. Simons of the Bureau of Medical Economics of the American Medical Association will present a paper dealing with service plans sponsored by the Firm Security Administration.

In addition to the secretaries and editors of state medical associations, it is expected that a number of presidents and other officers of state associations and county medical societies will be present on that occasion. Other physicians who may wish to attend will be heartily welcome.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status—S. 2412 has been reported to the House, a bill to provide benefits for the injury, disability, death or enemy detention of employees of contractors with the United States. H. R. 7568 has passed the House, a bill proposing to discharge more effectively the obligations of the United States under certain treaties relating to the manufacture and distribution of narcotic drugs, by providing for the domestic control of the production and distribution of the opium poppy and its products.

Bill Introduced—H. R. 7742, introduced by Representative Tolan, California, a bill (1) to inventory and mobilize all the economic resources of the United States including manpower, facilities, materials, technical and scientific knowledge, and natural resources for maximum use in the provision of military and essential civilian needs and (2) to adjust and stabilize the economy in accordance with the needs of full mobilization and other conditions created by war.

DISTRICT OF COLUMBIA

Change in Status—S. Res. 302 has been agreed to by the Senate, requiring the Federal Works Agency, the Public Health Service, the District commissioners and other government agencies and officials charged with the responsibility of providing the people of Washington and its environs with adequate hospital facilities to prepare and submit to the Senate a report. This report, which is to be made within fifteen days, is to set forth plans and specifications which have been adopted, and those which are under study and consideration as to their feasibility, possibility and availability, together with the present status of each project, actual or contemplated, and to give in detail the type of accommodations and facilities which are considered necessary to meet the situation existing and to rectify the conditions prevailing, including supplies and equipment of all kinds necessary to an immediate carrying out of the program in full.

MEDICAL ECONOMIC ABSTRACTS

MEDICAL CARE FOR RECIPIENTS OF PUBLIC ASSISTANCE UNDER THE SOCIAL SECURITY ACT

Federal grants to assist states in providing medical care for the aged, the blind and dependent children who are recipients of assistance under the Social Security Act are proposed by H. R. 7411, a bill introduced by Representative Coffey of Washington, July 20. At the option of the state, needy members of the household of such recipients may also be furnished medical care. An appropriation of \$18,000,000, it is proposed, will be authorized for the fiscal year to carry out this program, and thereafter each year a sum sufficient to carry out the purposes of the program will be made available. This federal money

will be used in making allotments to the several states which have developed plans that have been approved by the Social Security Board. As defined by the bill the term "medical care" includes only such physicians and nurses services, drugs and other medicines, prosthetic and other appliances, hospitalization and other services and supplies for treatment and care of the recipients of public assistance and needy members of their household as may be approved in regulations to be promulgated by the Social Security Board. Medical care may be provided directly either by the state or by other agency administering or supervising the administration of the plan, or indirectly through payments by the state or other agency to the person or persons furnishing such care. The bill is pending in the House Committee on Ways and Means.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Changes in Health Personnel—Dr Frederick G Hall, formerly of Galesburg, Ill., has been named assistant city health officer of Long Beach—Dr Paul G Buss, Los Angeles, has been appointed assistant county health officer of Orange County, Anaheim—Dr Lester S McLean, San Francisco, was named health officer of Solano County, August 3, succeeding Dr George O'Brien, Fairfield, resigned—Dr Roscoe C Mann, Los Angeles, at one time health officer of Santa Barbara County, has been appointed in charge of the Glendale district health unit, succeeding Dr John M Buchanan, Glendale, who has entered army service

School of Public Health Proposed—The Northern California Public Health Association recently appointed a committee—Drs William P Shepard, chairman, Fred T Foard, Bertram P Brown, Charles Edward Smith, Karl F Meyer, and Mr W Ford Higby and Mr Lawrence Arnstein—on the establishment of a Western school of public health According to *Western Public Health* the committee has made definite proposals to the University of California at Berkeley, including preparation of a tentative budget and plans to prepare and sponsor a bill in the 1943 state legislature which would ask for a special appropriation for the purpose

Tuberculosis Association Creates Heart Division—The Los Angeles Tuberculosis and Health Association has created a heart division to carry on a program of education and study so that adequate community facilities may be provided for the prevention of heart disease in Los Angeles The new service will be under the direction of Mr James G Stone, Los Angeles, executive secretary of the Los Angeles Tuberculosis and Health Association Members of the Los Angeles Heart Association will act as the advisory committee and Majorie Edwards, San Francisco, executive secretary of the California Heart Association, will direct the new program for the coming year Emphasis will be placed on establishing effective health educational programs on heart disease prevention in cooperation with the Tenth District of the California Congress of Parents and Teachers, on providing health education aids in cooperation with the city schools, on standardizing heart clinics and on promoting convalescent care for heart patients

DISTRICT OF COLUMBIA

Council to Oversee Students' Health—Wilson Teachers' College Washington, has formed a Health Council to check the health and physical condition of students and faculty, newspapers reported on September 27 The council includes two students, faculty members from different academic departments and from the physical education department, the college nurse, the manager of the cafeteria and the chief custodian Henry W Olson, Ph D, professor of biology, is chairman of the council

Annual Registration of Physicians Required—Every person holding a license to practice the healing art in the District of Columbia must register with the secretary-treasurer of the Commission on Licensure during the month of December of each year and pay a fee of \$2 Holders of more than one type of license must register each license separately A licensee who does not register and pay the fee will be subject to a penalty of \$5, if he fails to register and pay the penalty and continues to practice, he will at the end of ten days after December 31, be considered as practicing medicine without a license and penalized as otherwise provided in the healing arts practice act The secretary-treasurer of the Commission on Licensure must on or before December 1 mail to each licensee, at his last known address, a blank form for registration

IDAHO

State Medical Election—Dr Parley Nelson Rexburg was chosen president-elect of the Idaho State Medical Association at its annual meeting in September and Dr George O A Kellogg, Nampa was inducted into the presidency Dr Franklin B Jeppesen Boise, is the secretary

ILLINOIS

Postgraduate Conference—The Illinois State Medical Society sponsored a postgraduate conference at the Jefferson Hotel, Peoria, October 22 in cooperation with the Peoria County Medical Society The following program was presented

Dr Chester R Zeiss Chicago The Paraffin Wax Treatment of Burns
Dr James J Callahan Chicago The Minimum Requirement in Treatment of Fractures
Dr Arrie Bamherger Chicago Treatment of Soft Tissue Injuries
Dr Italo F Volini Chicago The Oral Intravenous and Intrabdominal Uses of Sulfonamides
Dr Warren H Cole Chicago Recognition and Treatment of Shock
Lieut Col Joel L Deuterman M C U S Army Camp Grant Treatment of War Gases
Dr Harold M Camp Monmouth and Lieut Col Randolph F Olmsted M C U S Army Chicago The Doctor Goes to War

Chicago

Postpone Construction of University Hospital—Construction of a million dollar hospital on the campus of the University of Chicago has been postponed until after the war newspapers reported on October 2 Part of the funds available for the new hospital will be released to care for charity patients at Albert Merritt Billings Hospital The proposed hospital for the study and treatment of contagious diseases will be located on a site donated by the University of Chicago on the east side of Drexel Boulevard, between Fifty-Eighth and Fifty-Ninth streets Three trust funds have been merged to build the hospital, which will be known as the Charles Gilman Smith Hospital under the terms of a trust fund established by Mrs Harriet G Smith, who died in 1896 The Smith trust fund has reached more than \$500,000, it was stated Trustees for the estate of the late Mrs Annie W Durand have pledged \$160,000, and the John R McCormick Memorial Institute for Infectious Diseases \$300,000 An order signed by Judge Cornelius Harrington, June 28, 1940, called for construction of the hospital within five years The proposal to use the current net income from Mrs Durand's estate for charity patients at the Billings Hospital was made by the Northern Trust Company, trustee for the estate Mrs Durand's will stipulated that funds were to be used for the construction of hospitals "in the poorest and most thickly settled parts" of Chicago Durand Hospital, on Wood Street, was built in 1913 and operated by the McCormick Institute but was discontinued in 1933 On October 1 Judge Harrington approved an order directing the trustee for the \$300,000 estate of Mrs Durand to donate part of the \$12,000 yearly net income for the treatment of poor patients suffering from communicable or contagious diseases

INDIANA

Dr Lawson Observes Ninety-Third Birthday—Dr Wilson T Lawson, Danville, county health officer and secretary of the Hendricks County Medical Society observed his ninety-third birthday September 3 Dr Lawson, who is still practicing, graduated at Miami Medical College, Cincinnati, in 1878

Dr Tucker Wins Scholarship—The 1942 scholarship of the Indiana Tuberculosis Association has been awarded to Dr Warren S Tucker, Indianapolis, entitling him to attend a six week course at the Trudeau School for Physicians at Saranac Lake, N Y Dr Tucker is in charge of tuberculin testing and case finding in schools and colleges for the Marion County Tuberculosis Association

State Medical Election—Dr Jacob T Oliphant Farmersburg, was chosen president-elect of the Indiana State Medical Association at its meeting, October 1, and Dr Carl H McCaskey, Indianapolis, was installed as president Other officers are Dr Arthur W Weyerbacher Indianapolis treasurer and Mr Thomas A Hendricks, Indianapolis secretary The next annual session is planned for Indianapolis

MASSACHUSETTS

Psychiatry Clinic Opened—The Boston Psychoanalytic Institute officially opened the Psychiatry Clinic at 82 Marlborough Street, Boston October 5 The clinic is to be conducted on a nonprofit basis and patients will be treated without charge or for a nominal fee It will accept and treat as patients those persons who can be psychiatrically considered as having 'civilian war neurosis' The purpose of psychotherapy will be chiefly to remove the traumatic symptoms in order to restore the patient as quickly as possible to his former occupation For this reason states an announcement, the treatment will consist of a short period of psychotherapy evolved for this purpose Psychoanalysis can and will be given only in rare cases A report of the clinic work and its results is to be published yearly and of research work in special articles periodically The clinic is planning to arrange courses and semi-

nars for the training of psychiatrists in the approach to these war neuroses and in the technic of this kind of psychotherapy. Drs M. Ralph Kaufman and Felix Deutsch, Boston, are directors of the clinic which is staffed by eighteen psychiatrists, five assistant psychiatrists and two psychologists, all of whom will devote part time without charge. A group of consulting physicians represents the specialties of endocrinology, medicine, surgery, dermatology, gynecology, otolaryngology, allergy, neurology and pediatrics. The Boston Psychoanalytic Institute was incorporated in 1936 under the laws of Massachusetts to establish and maintain an institution of learning in the field of psychoanalysis and related subjects, to teach and promote the study and practice of and cultivate knowledge in psychoanalysis, to establish and maintain a clinic for the practice and application of psychoanalysis and related subjects and to provide the names and facilities to accomplish any or all of these objectives. Until the present, its principal work has consisted of providing lectures, courses and seminars on psychoanalysis and related subjects with particular emphasis on the training of psychiatrists in the special technic and knowledge of psychoanalysis. The trustees of the institute unanimously voted on February 26 to operate a psychotherapeutic clinic for ambulatory patients whose problems are related to the present war situation.

MICHIGAN

Dr. James Bruce Now Vice President Emeritus—Dr. James D. Bruce, director of postgraduate medicine at the University of Michigan Medical School, Ann Arbor, since 1928 and vice president in charge of university relations since 1931, retired October 17 with the title "vice president emeritus." Dr. Bruce reached the retirement age of 70. Dr. Bruce graduated at the Detroit College of Medicine in 1896 and joined the faculty of the University of Michigan as assistant in internal medicine in 1904. He has served as director of internal medicine at the medical school, chief of the medical service at the university hospital, chairman of the division of health sciences since 1935 and chairman of the division of extramural services. Dr. Bruce is a member of the medical advisory committee, division of medical sciences of the National Research Council. He was a major in the U. S. Army during World War I.

NEW YORK

Lecture on Rheumatic Fever—Dr. John G. Fred Hiss, Syracuse, will deliver a lecture on rheumatic fever before the Cortland County Medical Society, November 20. The lecture is sponsored by the state department of health and the state medical society.

Annual Cancer Meeting—At the eighteenth annual meeting of the New York State Committee of the American Society for the Control of Cancer, Inc. in Rochester on October 6 the speakers were Dr. Arthur H. Paine on "Malignancy of the Genitourinary System" and Dr. Andrew H. Dowdy, "Role of Radiation Therapy in the Control of Malignant Disease." Dr. John M. Swan spoke on "The Five and Ten Year Survivals of Patients Treated in the Rochester Hospitals." Mrs. Louis H. Jacobs was elected secretary, Mr. Stephen E. Godden treasurer and Dr. Swan executive secretary, all of Rochester.

Personal—Paul O. Komora, since 1932 associate secretary of the National Committee for Mental Hygiene, has been appointed assistant secretary of the New York State Department of Mental Hygiene. Mr. Komora has been with the National Committee for Mental Hygiene since 1917. Dr. Raymond F. C. Kieb, former commissioner of correction, retired on September 15 as medical superintendent of the Institution for Male Defective Delinquents at Napanoch. Dr. Kieb served as superintendent of Matteawan State Hospital, Beacon, from 1913 to 1927, when he took a leave of absence for three and one-half years' service as commissioner of correction. He returned to Matteawan in 1930 and was transferred to Napanoch in 1940. Dr. Kieb will maintain an office in New York.

New York City

Bequest Provides for Free Blood Transfusions—Under the will of Mrs. Virgine Migeon Swift, widow of Dr. Edwin Elshia Swift, \$50,000 of a bequest to St. Luke's Hospital is to be used for free blood transfusions for patients unable to pay for them. The hospital will share with three other institutions the residuary estate of Mrs. Swift.

Minimum Heat for Buildings That Use Oil—The city department of health has fixed a minimum legal temperature of buildings heated by oil in the city at 65 F. Places heated by coal, gas or other means will still maintain the 68 degree minimum, according to the *New York Times*. The change was made because of the reduction in the available supply of fuel oil.

Lectures for the Public—The New York Academy of Medicine will open its annual series of lectures for the public November 12 with a talk by Robert R. Williams, D.Sc., on "Food and Civilization." The speaker for January 28 has not yet been decided but other lecturers will be:

Col. Edgar Erskine Hume, M.C., U. S. Army, Washington, D.C., December 10: War and Medicine.

Dr. Franz Alexander, Chicago: February 25: Aggressiveness—Individual and Collective.

Myrtle B. McGraw, Ph.D., New York: March 25: Growing Up Normally.

Dr. Bernard Gluck, Ossining, N.Y.: April 22: Crime and Punishment.

City Cancer Clinic Closed—The New York City Cancer Clinic at 124 East Fifty-Ninth Street has been closed because it has "outlived its usefulness." Patients at the clinic will be treated at clinics in other hospitals with modern facilities. With its present case load the clinic was operating at an excessive cost to the city, \$5.36 a visit, whereas under the new arrangement the cost will be less than \$2 a visit. The staff of the clinic will be distributed among other hospitals. Under the new arrangement, depending on the patient's residence, treatment will be given at Queens General Hospital, Morrisania City Hospital or Memorial Hospital or the Brooklyn Cancer Institute. The city cancer clinic is 19 years old.

Annual Campaign for Hospital Funds—The sixty-fourth annual campaign of the United Hospital Fund opened at the Hotel Waldorf-Astoria October 13. The speakers included James M. Landis, director of the Office of Civilian Defense, Dr. Philip D. Wilson, medical director of the Hospital for the Ruptured and Crippled, and Roy E. Larsen, president of the fund. Seventy-six voluntary nonprofit hospitals in the five boroughs of New York will be the beneficiaries of the campaign. More than 6,000,000 patient-days in the hospitals, including 2,000,000 days of free ward service, and 5,000,000 outpatient visits including 2,000,000 representing free service with medicine included, are the 1941 service figures for this hospital group.

NORTH CAROLINA

Report of Committee on Mental Hospitals—The creation of a central board to coordinate the control of state mental hospitals was one of the recommendations of a committee appointed in February to make an investigation of the State Hospital at Morganton. The committee submitted a report in August. The report also recommended the employment of a general superintendent of mental hygiene to be responsible for the direction of the state institutions and to establish and superintend a system of outpatient mental hygiene clinics at the various hospitals at the medical colleges within the state and at such community and public hospitals as may volunteer to cooperate. It was stipulated that the general superintendent of mental hygiene should be a doctor of medicine.

OKLAHOMA

Dr. Lowry Made Dean at Oklahoma—Dr. Tom Lowry, professor of clinical medicine, has been appointed dean of the University of Oklahoma School of Medicine, Oklahoma City, on a part time basis. He will serve from November 15 to July 1, 1943. Dr. Robert U. Patterson, who has been dean since 1935, is retiring on account of age.

Postgraduate Instruction—On October 16 the Oklahoma State Medical Association began a ten week program of postgraduate medical instruction in internal medicine. The program has been made possible through the financial cooperation of the Commonwealth Fund of New York and the Oklahoma State Department of Public Health. Dr. Luke W. Hunt, Chicago, is conducting the course. Meetings will be held in Tulsa each Friday night alternately at Hillcrest Memorial and St. John's hospitals. Similar meetings will be held in Pawhuska, Ponca City, Sapulpa and Stillwater. The course will include a discussion of chronic arthritis and allied conditions, gastrointestinal diseases, disorders of the heart, cardiovascular renal disease, the anemias and blood dyscrasias, chronic nontuberculous pulmonary disease, diabetes mellitus, sulfonamide drugs, nutritional disease and deficiency states, and endocrine disorders.

WEST VIRGINIA

Industrial Health Institutes—The committee on industrial health of the state medical association and the bureau of industrial medicine of the state department of health cooperated in a series of industrial health institutes in Bluefield, Charleston, Fairmont and Wheeling, October 20-23. Speakers included:

Dr. John W. Crosson, Charleston: Industrial Hygiene in West Virginia.

Dr. Emory R. Hayhurst, Columbus, Ohio: Control of Health in Industry.

Charles L. Heberlin, Charleston: Cost of Industrial Injuries.

Dr. Orlen J. Johnson, Chicago: The Responsibilities of American Medicine to War Production.

J. J. Bloomfield, Bethesda, Md.: Industrial Hygiene and War Production.

Van A. Bittner, Washington, D.C.: Labor's Evaluation of Public Health Service and Industrial Hygiene Among Workers in Industry.

WISCONSIN

State Medical Election—Dr Russell M Kurten, Racine, was chosen president-elect of the State Medical Society of Wisconsin at its annual meeting in September and Dr Francis E Butler, Menomonie, was installed as president. Mr Charles H Crownhart, Madison, is the secretary. The 1943 session will be held in Milwaukee in September, the dates to be decided later.

Industrial, Medical and Surgical Clinic—"Keep 'Em Working" will be the theme of the postgraduate industrial, medical and surgical clinic in Milwaukee, November 17, given under the auspices of the committee on industrial health and the council on scientific work of the state medical society in cooperation with the industrial hygiene unit of the state board of health. Among the speakers will be

Mr Harry A Nelson Milwaukee The Physician's Responsibility Under the Workmen's Compensation Act
Dr Merritt L Jones Wausau The Evaluation of Disability in Industrial Injuries
Dr James R Regan Milwaukee Knee Joint Injuries and Their Treatment
Dr Elston L Belknap Milwaukee Poisons in Industry
Dr Raymond W McNealy Chicago The Handicap of Hernia in Industry
Dr Chester C Schneider Milwaukee Reduction of Disabilities in Fracture Management
Dr Carl W Eberbach Milwaukee Traumatic Shock
Dr Harry W Sargeant Wauwatosa Hospital Facilities and Inadequacies During the Accelerated Program

Round table discussions will be held by

Dr Harry E Mock Chicago Skull Fractures
Dr Newell C Gilbert Chicago The Coronary Artery in Industry
Dr Herman C Schumm Milwaukee Rehabilitation Following Fractures
Dr Russell M Kurten Racine The Physical Examination in Industry
Dr Erwin R Schmidt Madison Injuries to the Scalp, Skull and Brain
Dr Eben J Carey Milwaukee Anatomical Considerations in Back Injuries
Dr John O Dieterle Milwaukee Intervertebral Disk Diseases
Dr Stephen E Gavin Fond du Lac Therapy of Burns
Dr John L Garvey Milwaukee Neuritis Following the Use of Serum
Dr William E Grove Milwaukee, Ear and Eye Complications of Craniofacial Injuries
Mr William D James president James Manufacturing Company Fort Atkinson, Health in Industry
Mr Andrew T Court General Motors Corporation Detroit Sickness Absenteeism in Industry

GENERAL

Western Surgical Cancels Meeting—The Western Surgical Association has canceled its meeting which was to be held in Memphis, Tenn., December 4-5.

Annals of Medical History to Be Suspended—Paul B Hoebler, Inc., announces that with the issue of November publication of the *Annals of Medical History* will be suspended.

Committee to Study Effect of Radio on Public Morale—A committee has been appointed to study radio broadcasting from the standard of morale and public health and to act as permanent consultant to the National Broadcasting Company. The committee will also make recommendations on how the network may better its efforts to promote national welfare and aid the war. Members of the committee, whose work will be supervised by James Rowland Angell, LL.D., educational counselor, are Dr Morris Fishbein, Editor of *THE JOURNAL*, chairman, Dr Henry R Viets, lecturer on neurology, Harvard Medical School Boston and Dr Winfred Overholser, professor of psychiatry, George Washington University School of Medicine, Washington, D.C.

Chemical Exposition—The National Chemical Exposition will be held at the Hotel Sherman Chicago, November 24-29. One feature of the exposition will be a symposium on electron microscopists with George L Clark, Ph.D., professor of chemistry, University of Illinois, Urbana, Ill., presiding. Vladimir K Zworykin, Ph.D., director of the electronic research laboratories of the Radio Corporation of America Manufacturing Company Camden, N.J., will speak on "The Electron Microscope in Relation to Chemical Research." Other speakers will include Charles G King, Ph.D., New York, on "Food and the Relation of Food to the Chemistry of Plants and the Soils," Leonard A Maynard, Ph.D., Ithaca, N.Y., "The Soil and Crop Basis of Better Nutrition," William A Albrecht, Ph.D., Columbia, Mo., "Soil Fertility and the Human Species," and P Gerald Kruger, Ph.D., Urbana, "The Cyclotron and Its Uses in Research."

Food and Drug Officials Organize for Emergencies—Food and drug officials of the New England states, New York and New Jersey organized at a meeting in Albany October 9 to provide protection for food and drugs in the event of enemy attack. Hermann C Lythgoe, B.S., director of the division of food and drugs of the Massachusetts Department

of Public Health Boston, was selected as chairman and Herbert Plank of the Dairy and Food Commission of Connecticut as secretary. The purpose of the organization is to give mutual assistance in the case of bombing or other catastrophes. Any single state might find itself lacking sufficient personnel to enforce laws for the prevention of the sale of unwholesome food and to make laboratory tests, according to the *New York Times*. It was proposed to have a central office where the officials of other states might ask assistance and where statistics might be kept. An executive committee composed of representatives of all states concerned will be in charge of the work.

Prize for Window Display on Psychiatry—A prize of \$100 is offered by the Menninger Foundation for Psychiatric Education and Research for the best suggestion for a window display in a New York bank presenting the uses and purposes of psychiatry. The window is 13 feet long and 6 feet high, and its deepest point about 8 feet, it curves so that it is narrower at the ends. It will be seen chiefly by laymen and hence the display should be in the nature of an educational theme convincingly and graphically presented. It should dramatize the way in which psychiatry can be or is being useful either in the present war emergency or in peacetime. The judges will be Dr George S Stevenson, New York, director of the National Committee for Mental Hygiene, Mr Albert D Lasker, New York, of Lord and Thomas and Dr Lawrence S Kubie, New York. Ideas should be submitted in detail preferably with drawings or diagrams, directly to Dr William C Menninger, director of the Menninger Clinic, Topeka, Kan., on or before Jan 31, 1943.

Central Society for Clinical Research—The annual meeting of the Central Society for Clinical Research will be held at the Drake Hotel Chicago, November 6-7. Among the speakers will be

Drs James Dewey Bisgard and Howard B Hunt Omaha Mechanism for the Action of X-Ray Therapy on Infection
Dr John M Adams Minneapolis Comparative Study of the Pathogenesis and Pathology of Pneumonitis in Infancy
Dr Louis R Limarzi, Chicago Effect of Arsenic (Fowler's Solution) on Erythropoiesis
Dr Raphael Isaacs Chicago Effect of Pectin on the Coagulation of Blood in Thrombocytopenic Conditions
Drs Edgar A Hines Jr and Lealides M Eaton Rochester Minn Experiences with Treatment of Migraine with Potassium Thiocyanate
Drs Eliot E Foltz Clifford J Barborak and Andrew C Ivy Chicago Influence of a Diet Deficient in the Vitamin B Complex on the Work Output of Trained Subjects Experimental Procedure
Drs Hans L Popper and Frederick Steigmann Chicago Causes of the Drop of the Plasma Vitamin A Level in Liver Diseases
Drs William C Olson and Heinrich Necheles Chicago Experimental Studies on Burns

A joint meeting of the Central Inter-Urban Clinical Club and the Central Clinical Research Club will be held on November 5.

New Journal on Gastroenterology—The American Gastroenterological Association on January 1 will publish the first issue of a new journal to be called *Gastroenterology*. It will be owned by the association but published by Williams and Wilkins Company, the subscription will be \$6 a year. Dr Walter C Alvarez, Rochester, Minn., will be the editor after June 1943, and Dr Andrew C Ivy, Chicago, will be the assistant editor. The editorial board will consist of Drs Abraham H Aaron, Buffalo, N.Y., Jacob A Bergen, Rochester, Minn., Henry L Bockus, Philadelphia, William C Boeck, Los Angeles, Burrill B Crohn, New York, Robert Elman, St. Louis, Edward Hollander, New York, Sara M Jordan, Boston, John L Kantor, New York, Byrl R Kirklin, Rochester, Minn., Paul Klemperer, New York, Frank H Lahey, Boston, Frank C Mann, Rochester, Minn., Herman J Moersch, Rochester, Minn., Walter L Palmer, Chicago, Julian M Ruffin, Durham, N.C., Rudolf Schindler, Chicago, Dwight L Wilbur, San Francisco and Victor C Myers, Ph.D., Cleveland. *Gastroenterology* invites for publication clinical and investigative contributions which are of interest to the general practitioner as well as the specialist and which deal with the diseases of digestion and nutrition. Manuscripts should be sent to Dr Andrew C Ivy, Gastroenterology, 303 East Chicago Avenue, Chicago. Letters regarding subscriptions and business matters should be addressed to Mr R S Gill, Williams and Wilkins Company, Baltimore.

CORRECTION—THE NEW DIRECTORY

St Elizabeth Hospital, La Fayette, Ind.—The new Seventeenth Edition of the American Medical Directory shows correctly that St. Elizabeth Hospital, La Fayette, Ind., is approved for intern training by the Council on Medical Education and Hospitals and approved for nurse training by the Indiana State Board of Nurse Examiners. It should also have indicated that the hospital is approved by the American College of Surgeons.

nars for the training of psychiatrists in the approach to these war neuroses and in the technique of this kind of psychotherapy. Drs M. Ralph Kaufman and Felix Deutsch, Boston, are directors of the clinic which is staffed by eighteen psychiatrists, five assistant psychiatrists and two psychologists, all of whom will devote part time without charge. A group of consulting physicians represents the specialties of endocrinology, medicine, surgery, dermatology, gynecology, otolaryngology, allergy, neurology and pediatrics. The Boston Psychoanalytic Institute was incorporated in 1936 under the laws of Massachusetts to establish and maintain an institution of learning in the field of psychoanalysis and related subjects, to teach and promote the study and practice of and cultivate knowledge in psychoanalysis, to establish and maintain a clinic for the practice and application of psychoanalysis and related subjects and to provide the names and facilities to accomplish any or all of these objectives. Until the present, its principal work has consisted of providing lectures, courses and seminars on psychoanalysis and related subjects, with particular emphasis on the training of psychiatrists in the special technique and knowledge of psychoanalysis. The trustees of the institute unanimously voted on February 26 to operate a psychotherapeutic clinic for ambulatory patients whose problems are related to the present war situation.

MICHIGAN

Dr. James Bruce Now Vice President Emeritus—Dr. James D. Bruce, director of postgraduate medicine at the University of Michigan Medical School, Ann Arbor, since 1928 and vice president in charge of university relations since 1931, retired October 17 with the title "vice president emeritus." Dr. Bruce reached the retirement age of 70. Dr. Bruce graduated at the Detroit College of Medicine in 1896 and joined the faculty of the University of Michigan as assistant in internal medicine in 1904. He has served as director of internal medicine at the medical school, chief of the medical service at the university hospital, chairman of the division of health sciences since 1935 and chairman of the division of extramural services. Dr. Bruce is a member of the medical advisory committee, division of medical sciences, of the National Research Council. He was a major in the U. S. Army during World War I.

NEW YORK

Lecture on Rheumatic Fever—Dr. John G. Fred Hiss, Syracuse, will deliver a lecture on rheumatic fever before the Cortland County Medical Society, November 20. The lecture is sponsored by the state department of health and the state medical society.

Annual Cancer Meeting—At the eighteenth annual meeting of the New York State Committee of the American Society for the Control of Cancer, Inc. in Rochester on October 6 the speakers were Dr. Arthur H. Paine on "Malignancy of the Genitourinary System" and Dr. Andrew H. Dowdy, "Role of Radiation Therapy in the Control of Malignant Disease." Dr. John M. Swan spoke on "The Five and Ten Year Survivals of Patients Treated in the Rochester Hospitals." Mrs. Louis H. Jacobs was elected secretary, Mr. Stephen E. Godden treasurer and Dr. Swan executive secretary, all of Rochester.

Personal—Paul O. Komora, since 1932 associate secretary of the National Committee for Mental Hygiene, has been appointed assistant secretary of the New York State Department of Mental Hygiene. Mr. Komora has been with the National Committee for Mental Hygiene since 1917. Dr. Raymond F. C. Kieb, former commissioner of correction, retired on September 15 as medical superintendent of the Institution for Male Defective Delinquents at Napanoch. Dr. Kieb served as superintendent of Matteawan State Hospital, Beacon, from 1913 to 1927, when he took a leave of absence for three and one-half years' service as commissioner of correction. He returned to Matteawan in 1930 and was transferred to Napanoch in 1940. Dr. Kieb will maintain an office in New York.

New York City

Bequest Provides for Free Blood Transfusions—Under the will of Mrs. Virginia Migeon Swift, widow of Dr. Edwin Elisha Swift, \$50,000 of a bequest to St. Luke's Hospital is to be used for free blood transfusions for patients unable to pay for them. The hospital will share with three other institutions the residuary estate of Mrs. Swift.

Minimum Heat for Buildings That Use Oil—The city department of health has fixed a minimum legal temperature of buildings heated by oil in the city at 65 F. Places heated by coal, gas or other means will still maintain the 68 degree minimum, according to the *New York Times*. The change was made because of the reduction in the available supply of fuel oil.

Lectures for the Public—The New York Academy of Medicine will open its annual series of lectures for the public November 12 with a talk by Robert R. Williams, D.Sc., on "Food and Civilization." The speaker for January 28 has not yet been decided, but other lecturers will be:

Col. Edgar Luskine Hume, M.C., U.S. Army, Washington, D.C. December 10. War and Medicine.

Dr. Franz Alexander, Chicago, February 25. Aggressiveness—Individual and Collective.

Myrtle B. McFarraw, Ph.D., New York, March 25. Growing Up Normally.

Dr. Bernard Glueck, Ossining, N.Y., April 22. Crime and Punishment.

City Cancer Clinic Closed—The New York City Cancer Clinic at 124 Last Fifty-Ninth Street has been closed because it has "outlived its usefulness." Patients at the clinic will be treated at clinics in other hospitals with modern facilities. With its present case load the clinic was operating at an excessive cost to the city, \$536 a visit, whereas under the new arrangement the cost will be less than \$2 a visit. The staff of the clinic will be distributed among other hospitals. Under the new arrangement, depending on the patient's residence, treatment will be given at Queens General Hospital, Morrisania City Hospital or Memorial Hospital or the Brooklyn Cancer Institute. The city cancer clinic is 19 years old.

Annual Campaign for Hospital Funds—The sixty-fourth annual campaign of the United Hospital Fund opened at the Hotel Waldorf-Astoria October 13. The speakers included James M. Landis, director of the Office of Civilian Defense, Dr. Philip D. Wilson, medical director of the Hospital for the Ruptured and Crippled, and Roy E. Larsen, president of the fund. Seventy-six voluntary nonprofit hospitals in the five boroughs of New York will be the beneficiaries of the campaign. More than 6,000,000 patient days in the hospitals, including 2,000,000 days of free ward service, and 5,000,000 outpatient visits including 2,000,000 representing free service with medicine included, are the 1941 service figures for this hospital group.

NORTH CAROLINA

Report of Committee on Mental Hospitals—The creation of a central board to coordinate the control of state mental hospitals was one of the recommendations of a committee appointed in February to make an investigation of the State Hospital at Morganton. The committee submitted a report in August. The report also recommended the employment of a general superintendent of mental hygiene to be responsible for the direction of the state institutions and to establish and superintend a system of outpatient mental hygiene clinics at the various hospitals at the medical colleges within the state and at such community and public hospitals as may volunteer to cooperate. It was stipulated that the general superintendent of mental hygiene should be a doctor of medicine.

OKLAHOMA

Dr. Lowry Made Dean at Oklahoma—Dr. Tom Lowry, professor of clinical medicine, has been appointed dean of the University of Oklahoma School of Medicine, Oklahoma City, on a part time basis. He will serve from November 15 to July 1, 1943. Dr. Robert U. Patterson, who has been dean since 1935, is retiring on account of age.

Postgraduate Instruction—On October 16 the Oklahoma State Medical Association began a ten week program of postgraduate medical instruction in internal medicine. The program has been made possible through the financial cooperation of the Commonwealth Fund of New York and the Oklahoma State Department of Public Health. Dr. Luke W. Hunt, Chicago, is conducting the course. Meetings will be held in Tulsa each Friday night alternately at Hillcrest Memorial and St. John's hospitals. Similar meetings will be held in Pawhuska, Ponca City, Sapulpa and Stillwater. The course will include a discussion of chronic arthritis and allied conditions, gastrointestinal diseases, disorders of the heart, cardiovascular renal disease, the anemias and blood dyscrasias, chronic nontuberculous pulmonary disease, diabetes mellitus, sulfonamide drugs, nutritional disease and deficiency states, and endocrine disorders.

WEST VIRGINIA

Industrial Health Institutes—The committee on industrial health of the state medical association and the bureau of industrial medicine of the state department of health cooperated in a series of industrial health institutes in Bluefield, Charleston, Fairmont and Wheeling, October 20-23. Speakers included:

Dr. John W. Crosson, Charleston. Industrial Hygiene in West Virginia.

Dr. Emory R. Hayhurst, Columbus, Ohio. Control of Health in Industry.

Charles L. Heaberlin, Charleston. Cost of Industrial Injuries.

Dr. Orlen J. Johnson, Chicago. The Responsibilities of American Medicine to War Production.

J. J. Bloomfield, Bethesda, Md. Industrial Hygiene and War Production.

Van A. Buttner, Washington, D.C. Labor's Evaluation of Public Health Service and Industrial Hygiene Among Workers in Industry.

WISCONSIN

State Medical Election—Dr Russell M Kuiten, Racine, was chosen president elect of the State Medical Society of Wisconsin at its annual meeting in September and Dr Francis E Butler, Menomonie, was installed as president. Mr Charles H Crownhart, Madison, is the secretary. The 1943 session will be held in Milwaukee in September, the dates to be decided later.

Industrial, Medical and Surgical Clinic—"Keep 'Em Working" will be the theme of the postgraduate industrial, medical and surgical clinic in Milwaukee, November 17 given under the auspices of the committee on industrial health and the council on scientific work of the state medical society in cooperation with the industrial hygiene unit of the state board of health. Among the speakers will be:

- Mr Harry A Nelson Milwaukee The Physician's Responsibility Under the Workmen's Compensation Act
- Dr Merrill L Jones, Wausau The Evaluation of Disability in Industrial Injuries
- Dr James R Regan Milwaukee Knee Joint Injuries and Their Treatment
- Dr Elston L Belknap Milwaukee Poisons in Industry
- Dr Raymond W McNally Chicago The Handicap of Hernia in Industry
- Dr Chester C Schneider Milwaukee Reduction of Disabilities in Fracture Management
- Dr Carl W Eberbach Milwaukee Traumatic Shock
- Dr Harry W Sargeant Wausau Hospital Facilities and Inadequacies During the Accelerated Program

Round table discussions will be held by

- Dr Harry E Mock Chicago Skull Fractures
- Dr Newell C Gilberl Chicago The Coronary Artery in Industry
- Dr Herman C Sebum Milwaukee Rehabilitation Following Fractures
- Dr Russell M Kuiten Racine The Physical Examination in Industry
- Dr Erwin R Schmidt Madison Injuries to the Scalp, Skull and Brain
- Dr Eben J Carey, Milwaukee Anatomical Considerations in Back Injuries
- Dr John O Dietrich Milwaukee Intervertebral Disk Diseases
- Dr Stephen E Gavin Fond du Lac Therapy of Burns
- Dr John L Garvey Milwaukee Neuritis Following the Use of Serum
- Dr William E Grovc Milwaukee Ear and Eye Complications of Cranioerebral Injuries
- Mr William D James president James Manufacturing Company Fort Atkinson Health in Industry
- Mr Andrew T Court General Motors Corporation Detroit Sickness Absenteeism in Industry

GENERAL

Western Surgical Cancels Meeting—The Western Surgical Association has canceled its meeting which was to be held in Memphis, Tenn., December 4-5.

Annals of Medical History to Be Suspended—Paul B Hoebler, Inc., announces that with the issue of November publication of the *Annals of Medical History* will be suspended.

Committee to Study Effect of Radio on Public Morale—A committee has been appointed to study radio broadcasting from the standard of morale and public health and to act as permanent consultant to the National Broadcasting Company. The committee will also make recommendations on how the network may better its efforts to promote national welfare and aid the war. Members of the committee, whose work will be supervised by James Rowland Angell, LL.D., educational counselor, are Dr Morris Fishbein, Editor of *THE JOURNAL*, chairman. Dr Henry R Viets, lecturer on neurology, Harvard Medical School, Boston, and Dr Winfred Overholser, professor of psychiatry, George Washington University School of Medicine, Washington, D. C.

Chemical Exposition—The National Chemical Exposition will be held at the Hotel Sherman, Chicago, November 24-29. One feature of the exposition will be a symposium on electron microscopists with George L. Clark, Ph.D., professor of chemistry, University of Illinois, Urbana, Ill., presiding. Vladimir K Zworykin, Ph.D., director of the electronic research laboratories of the Radio Corporation of America Manufacturing Company, Camden, N. J., will speak on "The Electron Microscope in Relation to Chemical Research." Other speakers will include Charles G. King, Ph.D., New York, on "Food and the Relation of Food to the Chemistry of Plants and the Soils"; Leonard A. Maynard, Ph.D., Ithaca, N. Y., "The Soil and Crop Basis of Better Nutrition"; William A. Albrecht, Ph.D., Columbia, Mo., "Soil Fertility and the Human Species," and P. Gerald Kruger, Ph.D., Urbana, "The Cyclotron and Its Uses in Research."

Food and Drug Officials Organize for Emergencies—Food and drug officials of the New England states, New York and New Jersey organized at a meeting in Albany, October 9, to provide protection for food and drugs in the event of enemy attack. Hermann C. Lythgoe, B.S., director of the division of food and drugs of the Massachusetts Department

of Public Health, Boston, was selected as chairman and Herbert Plank of the Dairy and Food Commission of Connecticut as secretary. The purpose of the organization is to give mutual assistance in the case of bombing or other catastrophes. Any single state might find itself lacking sufficient personnel to enforce laws for the prevention of the sale of unwholesome food and to make laboratory tests, according to the *New York Times*. It was proposed to have a central office where the officials of other states might ask assistance and where statistics might be kept. An executive committee composed of representatives of all states concerned will be in charge of the work.

Prize for Window Display on Psychiatry—A prize of \$100 is offered by the Menninger Foundation for Psychiatric Education and Research for the best suggestion for a window display in a New York bank presenting the uses and purposes of psychiatry. The window is 13 feet long and 6 feet high, and its deepest point about 8 feet, it curves so that it is narrower at the ends. It will be seen chiefly by laymen and hence the display should be in the nature of an educational theme, convincingly and graphically presented. It should dramatize the way in which psychiatry can be or is being useful either in the present war emergency or in peacetime. The judges will be Dr George S. Stevenson, New York, director of the National Committee for Mental Hygiene, Mr Albert D. Lasker, New York of Lord and Thomas, and Dr Lawrence S. Kubie, New York. Ideas should be submitted in detail preferably with drawings or diagrams directly to Dr William C. Menninger, director of the Menninger Clinic, Topeka, Kan., on or before Jan. 31, 1943.

Central Society for Clinical Research—The annual meeting of the Central Society for Clinical Research will be held at the Drake Hotel, Chicago, November 6-7. Among the speakers will be:

- Drs James Dewey Bisgard and Howard B. Hunt Omaha Mechanism for the Action of X-Ray Therapy on Infection
- Dr John M. Adams Minneapolis Comparative Study of the Pathogenesis and Pathology of Pneumonitis in Infancy
- Dr Louis R. Limarzi Chicago Effect of Arsenic (Fowler's Solution) on Erythropoiesis
- Dr Raphael Isaacs Chicago Effect of Pectin on the Coagulation of Blood in Thrombocytopenic Conditions
- Drs Edgar A. Hines Jr. and Lealde M. Eaton Rochester Minn. Experiences with Treatment of Migraine with Potassium Thioeyanate
- Drs Eliot E. Foltz Clifford J. Barborka and Andrew C. Ivy Chicago Influence of a Diet Deficient in the Vitamin B Complex on the Work Output of Trained Subjects: Experimental Procedure
- Drs Hans L. Popper and Frederick Siegmund Chicago Causes of the Drop of the Plasma Vitamin A Level in Liver Diseases
- Drs William C. Olson and Heinrich Necheles Chicago Experimental Studies on Burns

A joint meeting of the Central Inter-Urban Clinical Club and the Central Clinical Research Club will be held on November 5.

New Journal on Gastroenterology—The American Gastroenterological Association on January 1 will publish the first issue of a new journal to be called *Gastroenterology*. It will be owned by the association but published by Williams and Wilkins Company, the subscription will be \$6 a year. Dr Walter C. Alvarez, Rochester, Minn., will be the editor after June 1943, and Dr Andrew C. Ivy, Chicago, will be the assistant editor. The editorial board will consist of Drs Abraham H. Aaron, Buffalo, N. Y.; Jacob A. Barger, Rochester, Minn.; Henry L. Boeckus, Philadelphia; William C. Boeck, Los Angeles; Burrill B. Crohn, New York; Robert Elman, St. Louis; Edward Hollander, New York; Sara M. Jordan, Boston; John L. Kantor, New York; Byrl R. Kirklin, Rochester, Minn.; Paul Klemperer, New York; Frank H. Lahey, Boston; Frank C. Mann, Rochester, Minn.; Herman J. Moersch, Rochester, Minn.; Walter L. Palmer, Chicago; Julian M. Ruffin, Durham, N. C.; Rudolf Schindler, Chicago; Dwight L. Wilbur, San Francisco; and Victor C. Myers, Ph.D., Cleveland. *Gastroenterology* invites for publication clinical and investigative contributions which are of interest to the general practitioner as well as the specialist and which deal with the diseases of digestion and nutrition. Manuscripts should be sent to Dr Andrew C. Ivy, Gastroenterology, 303 East Chicago Avenue, Chicago. Letters regarding subscriptions and business matters should be addressed to Mr R. S. Gill, Williams and Wilkins Company, Baltimore.

CORRECTION—THE NEW DIRECTORY

St Elizabeth Hospital, La Fayette, Ind.—The new Seventeenth Edition of the American Medical Directory shows correctly that St Elizabeth Hospital, La Fayette, Ind., is approved for intern training by the Council on Medical Education and Hospitals and approved for nurse training by the Indiana State Board of Nurse Examiners. It should also have indicated that the hospital is approved by the American College of Surgeons.

The Call-Up of Doctors for the War

On the outbreak of war a committee of leading members of the medical profession was set up by the minister of health to advise on measures to secure economy in medical manpower and on the allocation of doctors between the fighting forces and the civilian population. The committee recommended the setting up of a committee in each of the civil defense regions into which the country has been divided charged to secure the maximum cooperation to meet civilian and service needs in the area and to eliminate underemployment and overlapping of doctors. This was done. Other recommendations adopted included the raising of the military age limit for doctors from 41 to 46 years and compulsory powers to transfer the staff from one hospital to another. The transference of general practitioners from one area to another where they are more urgently required was considered. But the difficulties were found to be insuperable because of the personal nature of the services rendered and the financial problems involved. In a later report further measures were recommended to meet the irreducible needs of the fighting forces. The following were adopted: a percentage reduction of hospital staffs, greater mobility in the use of the remaining staffs between one hospital and another, recruitment of one hundred physicians serving in mental institutions, restriction to six months of the period for which newly qualified doctors hold hospital appointments before entering the fighting services, review of public health staffs so as to release more doctors for the services, compulsory recruitment of women doctors. More than eight hundred alien doctors—Poles, Czechs, Germans and Austrians—have been employed. Medical schools have been asked to reduce their clinical course by six months and to discontinue postgraduate courses which involve the whole time attendance of medical men and women for a considerable period.

THE EFFECT ON CIVILIAN PRACTICE

Discussing these reports at a press conference the minister of health, Mr. Ernest Brown, said that in view of the increasing demands of the fighting forces, the women's auxiliary services, the civil defense services and war factories the civil population must in the coming winter manage with considerably fewer doctors. Before the war we had one doctor to 2,200 of the population, now the number was one to 2,700. Moreover, the doctors who remained were mainly the older men. Nor could the present proportion be maintained as the call up continued. But we were much better off than the Germans. He asked patriotic citizens to lighten as much as possible the burden on overworked doctors. Dr. G. C. Anderson, secretary of the Central Medical War Committee, asked them to help by observing the following rules: 1. Call the doctor early in the illness and early in the day—if possible not later than 10 a. m. 2. Send an accurate message, including exact address and concise information about the illness. 3. If you can travel, visit the doctor rather than ask him to come.

A Chair of Child Health

The last of the many munificent gifts to medicine of the automobile magnate Lord Nuffield is an offer from his Provincial Hospital Trust of \$75,000 toward the cost of establishing a chair of child health at King's College, Newcastle-on-Tyne.

The senate and court of the university have accepted the proposal with gratitude. They have appointed Dr. J. C. Spence as professor. The council of King's College has announced that it will provide him with the assistance necessary for creating a full teaching and research department. The Royal Victoria Infirmary and the Babies Hospital will cooperate with King's College by providing all possible facilities for the new department, which will be concerned with the preservation and restoration of the health of children. The department will provide undergraduate and postgraduate teaching in child health and the diseases of childhood. It will be a center of research and will be at the disposal of the public health and education authorities for advice and consultation in the conduct of their child welfare and school medical services. This is the first example of a chair of the kind in this country, though there have long been lecturers on pediatrics.

Red Cross Harvard Field Hospital Transferred to the American Army

At the beginning of the war Harvard University made an offer to Britain of funds and workers for research in any field that might contribute toward winning the war. We replied that there was a need for a study of wartime epidemics. It was agreed to establish an organization with three distinct activities: (1) a hospital for patients with communicable diseases, (2) research laboratories for the study of clinical problems and epidemiology, (3) a field organization for studies in epidemiology. The American Red Cross Harvard Field Hospital Unit was therefore established in England in 1940. It represented a combination of American Red Cross work with research by Harvard University. It was provided, staffed and financed by the American Red Cross. Harvard provided the laboratory, and the British Ministry of Health prepared the site, erected the buildings and shared in the operating cost.

In January 1941 the field staff of the hospital was working on the control of epidemics in this country. In September 1941 the hospital admitted its first patients. Mobile units have covered a wide variety of infectious diseases in many parts of England, Scotland and northern Ireland. Last year a unit was in Bristol dealing with a paratyphoid outbreak and recently one went to Glasgow in connection with an outbreak of smallpox there.

The entry of America into the war and the stationing of its troops in Britain has involved the provision of hospitals for them in this country. The American Red Cross Harvard Hospital has therefore been taken over by the American Army in Britain. It will be the central laboratory for the American forces. After the war the hospital will be turned over by the American Red Cross and Harvard University to the British Ministry of Health for the benefit of the people of Britain.

A Year's Vital Statistics

The Registrar General's Statistical Review for 1939 is in type, but because of the paper shortage it is not intended to put it on sale to the public as usual. Some copies have been printed for official use and are available on loan to persons having an acknowledged interest in vital statistics. An official summary shows that the number of live births during the year was 619,352, giving a birth rate of 14.9 per thousand persons living. This rate was 0.2 below that for 1938 and the same as that for 1937 and 0.5 above that for 1933, the lowest ever recorded. The death rate (excluding noncitizens from the outbreak of war in September) was 12.1 per thousand living, 0.5 above that for 1938 but 0.5 below that for 1937. When allowance is made for the fact that the proportion of old persons is increasing every year, the resulting corrected figure for the standardized death rate was 8.5, an improvement of 0.5 on the

previous best record, which was reached in 1935. The mortality of children under 1 year of age was 50 per thousand live births, the lowest on record and 3 below that for 1938, the previous best.

Mortality from infectious and parasitic diseases was 1.05 per thousand, an increase of 0.04 on the previous year, which was the lowest on record. The standardized death rate from tuberculosis fell to 5.95 per million of population, an improvement of 7 over the previous record. For pneumonia and nephritis the standardized rates for each sex showed substantial improvement. The cancer death rate, standardized for the increasing age of the population, decreased from 1,005 per million of the previous year to 989. Maternal mortality, including deaths from abortion, declined for the fifth year in succession, reaching a new low level of 2.47 per thousand live and still births. The rates for the five years 1934-1938 were respectively 3.78, 3.37, 3.16, 2.72 and 2.62. Thus the statistics for the national health in the year which includes the first four months of the war are very satisfactory.

Prof C R Harington, FRS

C R Harington, FRS, director of the Graham Laboratories and professor of pathologic chemistry, University College, London, has been appointed director of the National Institute for Medical Research in succession to Sir Henry Dale, president of the Royal Society. It is nearly twenty years since Professor Harington came to the Medical School of University College after working with Meakins, Burger and Van Slyke, and in that period a steady stream of research has flowed from the department of pathologic chemistry. His first ten years were mainly occupied with the chemistry of the thyroid gland, and within four years he published his classic paper on the synthesis of thyroxine, which placed him at once in the first rank. But he did not confine himself to purely chemical problems. In 1933 appeared his monograph on the thyroid, another classic, in which he stated with clarity and completeness the existing knowledge of the chemistry, physiology and functional pathology of the thyroid and made a forecast that the cause of hyperthyroidism would be found outside the thyroid, indicating the anterior lobe of the pituitary as the possible source of the stimulus. This view was received with some incredulity but was justified by the subsequent discovery of the thyrotropic hormone by Collip. In 1935 he synthesized glutathione and began a series of papers on the basis of immunology. No one is so completely fitted for his new post, most important in medical research in this country. The loss to University College of a man who not only was great as an original investigator but whose advice by all who were undertaking research was eagerly sought and freely given is much deplored.

Reform in the Teaching of Anatomy

In a joint communication to the *British Medical Journal* five teachers of anatomy suggested a reduction in the amount of descriptive anatomic detail taught to students. This suggestion received support in correspondence which followed in the *British Medical Journal*. These teachers have now written again, saying that time in the curriculum is needed for a broad education in structural organization with its functional implications. Knowledge of the descriptive detail should be built on this. For example, it is far better that the student should learn the plan of the construction of nerve plexuses through an understanding of its nature than by memorizing a system of apparently arbitrary interconnections. There should be a sound knowledge of the differentiation and growth of tissues, and histologic detail should be studied concurrently with gross structure. In the last twenty years there has been some pruning in the teaching of descriptive detail, but much still remains to be done.

Physicians' Fees in Greece Paid in Kind

The Ankara correspondent of the *Times* reports that the famine in Greece is producing incongruous as well as tragic consequences. This is illustrated by an incident which arose between the Greek minister of health and the Medical Association of Athens. The association recently decided that, because of the severe depreciation of the Greek currency, medical fees should be paid not in money but in kind. On what basis the fee should be calculated was not determined. The minister of health objected that this decision was incompatible with professional decorum, but the association replied that even physicians must live.

BUENOS AIRES

(From Our Regular Correspondent)

Oct 3 1942

Organize Board for Protection of Chilean Children

There is an annual birth rate of about 100,000 infants in Chile. About 25,000 mothers are delivered in maternity hospitals and 17,000 in their own homes. About 60,000 infants are properly nursed at home and 55,000 are nursed with the aid of reliable institutions. There are 400,000 children in the preschool age, 120,000 belong to well-to-do families and 7,000 or 8,000 have the aid of reliable institutions. There are about 900,000 children of school age. About 350,000 of these children belong to more or less rich families and about 48,000 have the aid and care of the medical department of the General Center of Public Health. Negotiations for organizing a board with the name of Consejo Superior de Proteccion a la Maternidad a la Infancia y a la Adolescencia are in progress. It will be formed with members of the ministries of Public Health, Justice and Education and will carry on work for the health, social care and education of mothers, infants and adolescents. The Ministry of Public Health recently organized a Central Department of Health for mothers and children.

National Conference for Welfare of Children

The second National Conference for Welfare of Abandoned Children and Delinquent Youths was held on September 25 in Buenos Aires in celebration of the fiftieth anniversary of the foundation of the Patronato de la Infancia of Argentina. The topics discussed were laws for adoption of children, work of minors, establishment of centers for social guidance and care of children, money given to private social and educational institutions for children, vagrancy, special women inspectors and prevention of abandonment of children.

Crusade Against Malaria in Bolivia

An American sanitary mission will visit Bolivia in the near future with the aim of inaugurating a crusade against malaria in Bolivia. Dr Eugene Payne will be at the head of the mission. Dr Wendell S. Dove, substitute director of the Rockefeller office, will be a member.

Department of Sanitation

A department for propaganda and education on matters of sanitation was recently established in the Ministry of Public Health in Paraguay. Dr Raul Peña was appointed head of the department.

Personals

Dr Nicolas Romano, professor of clinical medicine of the Faculty of Medicine of the University of Buenos Aires, was recently appointed president of the Asociacion Medica Argentina. —An Argentine medical delegation was sent to the Chilean universities last May. Dr Leon S. Morra, dean of the Faculty of Medicine of Cordoba, was the president of the delegation. —Dr Manuel Enrique Varela was recently appointed to the chair of embryology and histology at the Faculty of Medicine of the University of Buenos Aires to succeed the late Dr Pedro Rojas.

Deaths

Joseph Clar Beck * Chicago, College of Physicians and Surgeons, Chicago 1895, in 1900 joined the department of laryngology, rhinology and otology at his alma mater, now known as the University of Illinois College of Medicine, where he had been associate professor of laryngology, rhinology and otology emeritus since 1932, a member of the American Board of Otolaryngology, specialist certified by the American Board of Plastic Surgery, chairman of the Section on Laryngology, Otology and Rhinology of the American Medical Association, 1919-1920, a member and past president of the American Laryngological, Rhinological and Otological Society, the American Academy of Ophthalmology and Otolaryngology and the American Bronchoscopic Society, member of the American Laryngological Association, the American Otological Society, Inc., the Society of Plastic and Reconstructive Surgery and the American Broncho-Esophagological Association, consultant for the Chicago League for the Hard of Hearing, fellow of the American College of Surgeons, during World War I served as a lieutenant colonel in the French division of the Czechoslovakian army in charge of American Red Cross Hospital number 113 at Cognac, France, and was later transferred to Prague, Czechoslovakia, lieutenant colonel in the medical reserve corps, appointed associate dean of education at the Illinois Eye and Ear Infirmary in 1940, consultant in the eye, nose and throat department of the Veterans Administration, Hines, Ill., from 1927 to 1938, for eighteen years attending surgeon in the eye, nose and throat department of Cook County Hospital on the staffs of the Michael Reese, Hennrotin and the Mount Sinai hospitals, in 1931 received a gold medal from the American Academy of Ophthalmology and Otolaryngology, author of "Fifty Years of Medicine," "Applied Pathology of Nose, Throat and Ear" and "Atlas of Radiology of Ear, Nose and Throat", co author, with Dr. Ira Frank, of "Stereoscopic Atlas of Plastic Surgery of Face, Head and Neck", aged 72, died, October 20, of carcinoma.

Winfield Scott Hall, Berwyn, Ill., Northwestern University Medical School, Chicago 1888, head of the department of biology Haverford (Pa.) College from 1889 to 1893, professor of physiology from 1895 to 1919 and since then professor of physiology emeritus at his alma mater, where he had been junior dean from 1902 to 1913, lecturer on physiology at the Y. M. C. A. College, Chicago, from 1898 to 1917, exchange professor at the Universite Internationale, Brussels, Belgium, from 1921 to 1927, gave health talks at military schools, academies and colleges under the auspices of the U. S. Public Health Service from 1919 to 1929, chairman of the Section on Pathology and Physiology of the American Medical Association, 1904-1905, and member of the House of Delegates in 1907, member of the American Physiological Society and the International Congress on Tuberculosis, president of the American Academy of Medicine, 1904-1905, lecturer on dietetics at the Mercy Hospital School for Nurses from 1896 to 1918 and the Wesley Hospital School for Nurses from 1903 to 1918, author of "Textbook of Physiology, Normal and Pathological" and "Nutrition and Dietetics", aged 81, died, October 2, of uremia.

Herman Besser, New York, Bellevue Hospital Medical College, New York, 1897, member of the Medical Society of the State of New York and the American College of Radiology, specialist certified by the American Board of Radiology, Inc., held the chair of electroradiotherapy at the New York Polytechnic Medical School and Hospital, 1905-1906, chief radiologist at the Washington Heights Hospital, 1914-1915, consultant to the Columbus Hospital, director of the x-ray department of the Jewish Memorial Hospital, 1915-1916, since 1932 attending roentgenologist to the Lutheran Hospital, formerly editor of the "Skiagraphic Atlas", inventor of the Besser x-ray tube, aged 71, died, October 4, in the West Hill Sanitarium of coronary thrombosis.

Gilman Dubois Frost, Hanover, N. H., Dartmouth Medical School, Hanover 1892, Harvard Medical School, Boston, 1892, member of the New Hampshire Medical Society, lecturer of anatomy at his alma mater, 1893-1894, professor of anatomy from 1894 to 1910, secretary and treasurer of the school from 1896 to 1904 and secretary from 1904 to 1909, professor of clinical medicine from 1910 to 1937 and since then professor of clinical medicine emeritus, formerly attending physician on the staff of the Mary Hitchcock Memorial Hospital, aged 78, died, October 8, of arteriosclerosis.

Arthur John Huey * New York, University and Bellevue Hospital Medical College, New York, 1902, assistant in laryngology from 1905 to 1910, instructor from 1910 to 1915 and

since then lecturer at his alma mater, which is now known as the New York College of Medicine, consulting otolaryngologist for the U. S. Public Health Service, contract surgeon in the U. S. Army during World War I, aged 62, died, September 28, in the Park West Hospital of cirrhosis of the liver and ascites.

John Goldesbrough McEachem Jr., Racine, Wis., Rush Medical College, Chicago, 1865, member of the State Medical Society of Wisconsin, for many years served as a member of the municipal board of health and as city physician, in 1932 donated a chapel and library to St. Luke's Hospital, of which he was one of the founders and for many years president of the hospital board of directors, aged 96, died, September 10, of arteriosclerosis.

Steuart Brown Muncaster * Washington, D. C., Georgetown University School of Medicine, Washington 1885, formerly associate professor of ophthalmology at his alma mater, member of the American Academy of Ophthalmology and Otolaryngology, one of the founders of the District of Columbia Society for the Prevention of Blindness, aged 85, died, September 11, in the Episcopal Eye, Ear, and Throat Hospital of coronary occlusion.

Thomas Harrison Carmichael, Tufts College, Mass., Hahnemann Medical College and Hospital, Philadelphia, 1886, chairman of the Committee on the Revision of Homoeopathic Pharmacopoeia of the United States in 1914 and 1936 and author of the preface in 1936, past president of the American Institute of Homoeopathy, aged 84, died, October 9, in a hospital at Cincinnati as the result of injuries received in a fall.

John Watson Cathcart * El Paso, Texas, Northwestern University Medical School, Chicago, 1903, specialist certified by the American Board of Radiology, Inc., member of the American Roentgen Ray Society, Radiological Society of North America, Inc., American College of Radiology and the American Radium Society, veteran of the Spanish-American War, aged 64, died, September 13, of aplastic anemia.

Alfred Plummer Roope, Columbus, Ind., Louisville (Ky.) Medical College, 1894, member of the Indiana State Medical Association, fellow of the American College of Surgeons, served overseas as a lieutenant colonel in the medical corps of the U. S. Army during World War I, aged 73, died, October 2, in the Veterans Administration Facility, Bay Pines, of cerebral hemorrhage.

Walter Prince Keene, Fontana, Calif., Georgetown University School of Medicine, Washington, D. C., 1900, veteran of the Spanish-American War and World War I, formerly on the staff of the Veterans Administration Facility, Sawtelle, aged 72, died, September 4, in the Veterans Administration Facility, Fort Lyon, Colo., of cerebral hemorrhage and coronary sclerosis.

Louis Collins Johnson * Brooklyn, Western Reserve University School of Medicine, Cleveland 1914, clinical professor of medicine at the Long Island College of Medicine since 1941, on the staff of the Long Island College Hospital, aged 58, died, September 25, in the Brooklyn Hospital of subdural hematoma and postoperative circulatory collapse.

Samuel Eder Last * Brooklyn, University and Bellevue Hospital Medical College, New York, 1921, specialist certified by the American Board of Urology, Inc., member of the American Urological Association, on the staffs of the Evanston Deaconess Hospital and the Greenpoint Hospital, aged 43, died, September 26, of coronary thrombosis.

Edward Burgin Shellenberger, Mountville, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1902, formerly on the staffs of the Warren (Pa.) State Hospital and the Danville (Pa.) State Hospital, aged 65, died, September 8, in the General Hospital of Monroe County, East Stroudsburg, of mesenteric thrombosis.

Richard West Cooney * Erie, Pa., Georgetown University School of Medicine, Washington, D. C., 1923, specialist certified by the American Board of Otolaryngology, chief of the department of otolaryngology, St. Vincent's Hospital, aged 47, died, September 22, of coronary thrombosis while moose hunting in northern Canada.

Hans Christian Ericksen, Soldiers Grove, Wis., Minneapolis College of Physicians and Surgeons, 1907, served overseas as a captain in the medical corps of the U. S. Army during World War I, received the Croix de Guerre from the French government, aged 65, died, September 18, of bronchopneumonia.

Thomas Everett Bullard * Schuylerville, N. Y., College of Physicians and Surgeons, New York 1895, served as health officer of the village of Schuylerville and the towns of Saratoga and Northumberland, for many years president of the board of education, aged 79, died, September 19, of arteriosclerosis.

John Christopher Grabau, Buffalo, University of Buffalo School of Medicine, 1914, member of the Medical Society of the State of New York, served in the medical corps of the U S Army during World War I, aged 53, died, August 16, of coronary thrombosis and hypertension

Spencer Boyd McClary Sr, Etowah, Tenn, Memphis Hospital Medical College, 1904, served overseas in the medical corps of the U S Army during World War I, examining officer for the county Selective Service System, aged 59, died, September 28, of coronary thrombosis

Norman Briton Sowell @ Briarcliff Manor, N Y, Temple University School of Medicine, Philadelphia, 1926, surgeon and head of the medical assistant department of the Edgewood Park School, a junior college for girls, aged 43, died, October 3, of pulmonary infarct and endocarditis

Edward Leroy Kannary, St Paul, McGill University Faculty of Medicine, Montreal, Que, Canada, 1900, member of the Minnesota State Medical Association, aged 70, on the staff of St. Luke's Hospital where he died, September 23, of carcinoma of the pancreas

James Thomas Williams @ Wilkes-Barre, Pa, Jefferson Medical College of Philadelphia, 1904, formerly pathologist, associate surgeon and chief surgeon at the Wilkes-Barre General Hospital, aged 64, died, September 30, of coronary occlusion, at his home in Kingston

John Keller Griffith @ Slidell, La, Medical Department of Tulane University of Louisiana, New Orleans, 1907, formerly representative from the Sixth Congressional District, served during World War I, aged 59, died, September 25, of coronary thrombosis

Ludwig Ilse, St. Petersburg, Fla, Chicago College of Medicine and Surgery, 1912, member of the Illinois State Medical Society, veteran of the Spanish-American War, aged 69, died, September 8, of carcinoma of the prostate with metastases

Jesse Earl King, Kilgore, Texas, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910, served during World War I, aged 62, died, September 12, in a hospital at Dallas of malignant brain tumor

Conrad G Hoell, Camden, N J, University of Pennsylvania Department of Medicine, Philadelphia, 1882, formerly a druggist, at one time member of the city board of education, aged 82, died, September 24, of cardiovascular renal disease

Benjamin E Cline, Strawberry Plains, Tenn, University of Louisville (Ky) Medical Department, 1894 member of the Tennessee State Medical Association, aged 72, died, September 10, in a hospital at Jefferson City of angina pectoris

Walter Winfield Looney, Salem, Ore, Willamette University Medical Department, Salem, 1906, aged 67, for many years on the staff of the Oregon State Hospital, where he died, September 14, of gastric hemorrhage and gastric ulcer

Charles Taylor Robertson, Toronto, Ont, Canada, University of Toronto Faculty of Medicine, 1939, captain in the Royal Canadian Army Medical Corps, aged 31, was killed while in active service in the Dieppe raid in France

Charles Griffin Miller, Southport, Conn, University of Buffalo School of Medicine, 1896, veteran of the Spanish-American War, aged 74, died, September 1, in St. Luke's Hospital, New York, of carcinoma of the rectum

Bert Vivian Chance, Windfall, Ind, Medical College of Indiana, Indianapolis, 1897, member of the Indiana State Medical Association, served overseas during World War I, aged 69, died, September 14, of coronary occlusion

George Harris Boyer, Allentown, Pa, University of Maryland School of Medicine, Baltimore, 1902, member of the Medical Society of the State of Pennsylvania, aged 76, died, September 16, of arteriosclerotic heart disease

James S Austin, Oak Ridge, Miss, Kentucky School of Medicine, Louisville, 1878, at various times served as a representative in the state legislature, aged 86, died, September 19, of arteriosclerosis and cerebral hemorrhage

Charles Nevers Raymond @ Providence, R I, College of Physicians and Surgeons, New York, 1877, an Affiliate Fellow of the American Medical Association, aged 88, died, September 19, of carcinoma of the tongue

Willie B Doughty, Berry, Ala, Louisville (Ky) Medical College, 1896, member of the Medical Association of the State of Alabama, aged 68, died, September 15, in the Druid City Hospital, Tuscaloosa, of acute septicemia

Henry Stanley Hollenbeck, Milwaukee, Northwestern University Medical School, Chicago, 1907, for many years a

medical missionary in Cuma Angola, Africa, aged 64, died, September 16, in Chicago of pneumonia

Percy Edward Whiffen @ McClure, Pa, Medico-Chirurgical College of Philadelphia, 1911, past president of the Mifflin County Medical Society, aged 66, died, October 4, in the Lewis-town (Pa) Hospital of nephritis

Eleanor Van Ness Van Alstyne, Woodstock N Y, Cornell University Medical College, New York, 1916, aged 61, died, September 17, of lobar pneumonia and cerebral hemorrhage

Robert C Cunningham, Booneville, Miss, Medical Department of Tulane University of Louisiana, New Orleans, 1892, aged 84, died, September 4, of chronic interstitial nephritis

Robert Potts White, Jersey City, N J, Columbia University College of Physicians and Surgeons, New York, 1905, aged 63, died, September 15, of hypertensive heart disease

Parker Myles Ward, Houlton, Maine, Harvard Medical School, Boston, 1898, member of the Maine Medical Association, aged 69, died, September 8, of coronary disease

Hughes-Bayne Hoyle, Manteo, N C, North Carolina Medical College, Davidson, 1896, mayor of Manteo, aged 71, died, September 7, presumably of coronary occlusion

George Anthony Davis, Stratford, Conn, Jefferson Medical College of Philadelphia, 1903, aged 60, died, September 21, in New Haven of arteriosclerosis and hypertension

Martin Casselman Rutherford, Rochester, N Y, McGill University Faculty of Medicine, Montreal, Que, Canada, 1879, aged 86, died, October 5, of coronary occlusion

Maxwell Tabacnic, St. Louis, St. Louis College of Physicians and Surgeons, 1907, aged 60, died, September 24, in the Missouri Baptist Hospital of ascending myelitis

James Nelson Bartholomew, Santa Ana, Calif, Medical College of Ohio, Cincinnati, 1882, aged 84, died, September 15, of chronic myocarditis and diabetes mellitus

Robert E Groce, Bernie, Mo, St. Louis College of Physicians and Surgeons, 1909, aged 57, died, September 5, in Doniphan of cerebral hemorrhage

Boley John Green, Drew, Miss, Memphis (Tenn) Hospital Medical College, 1908, aged 72, died, August 29, in Winter Park, Fla, of cirrhosis of the liver

John F Armentrout @ Roanoke, Va, University of Maryland School of Medicine, Baltimore, 1903, aged 75, died, September 28, of heart disease

Ernest Bland Van Arsdell, Louisville, Ky, Louisville Medical College, 1903, aged 64, died, October 1, in St. Joseph Infirmary of pneumonia

Steven Joseph Conway @ Chicago, Chicago College of Medicine and Surgery, 1917, aged 49, died, September 26, of heart disease

Peter Campbell McEwen, Detroit, Detroit College of Medicine, 1895, aged 78, died, September 21, of cerebral hemorrhage

Frank Ira Smith, Athens, Pa, Jefferson Medical College of Philadelphia, 1889, aged 80, died, September 5, of coronary occlusion

Robert Bagley Cralle Jr, Farmville, Va, Medical College of Virginia, Richmond, 1931, aged 39, died, September 26

George S Barger, Purcell, Okla, Marion-Sims College of Medicine, St. Louis, 1896, aged 67, died, September 15

William Jonas Smothers, Cedarbluff, Miss, Medical College of Alabama, Mobile, 1885, aged 83, died, August 28

William L Helsel, Scalp Level, Pa, Eclectic Medical Institute, Cincinnati, 1896, aged 69, died, September 12

Harvey W Bodamer, Medina, N Y, University of Buffalo School of Medicine, 1906, aged 62, died, September 21

Antoine Valentine Delaporte, Toronto, Ont, Canada, Trinity Medical College, Toronto, 1884, died recently

DIED WHILE IN MILITARY SERVICE

Daniel John Hogan, Boston, Tufts College Medical School, Boston, 1920, member of the Massachusetts Medical Society, formerly assistant visiting physician at the Boston City Hospital, was commissioned a major in the medical reserve corps of the U S Army and was called to active service April 11, 1941, was stationed at the Tilton General Hospital, Fort Dix, N J, where he died, August 15, of carcinoma of the sigmoid, aged 55

THE CONDITIONED REFLEX TREATMENT OF ALCOHOLISM

To the Editor—I read with considerable interest the articles on the treatment of chronic alcoholism by Lemere and others and by Miller in *THE JOURNAL*, September 26

For the past ten years I have had gratifying success in producing cures of many years' duration in the treatment of chronic alcoholism by establishing a "conditioned reflex" under hypnosis. I wish to call attention to the successful use of suggestive therapy in the treatment of chronic alcoholism. The various combinations of suggestive therapy are used to speed up an otherwise slow process and are used to create an aversion to the sight, smell, taste and thought of alcohol.

Briefly, the following procedure is used. A state of heightened suggestibility is induced with deep hypnosis as it is scientifically applied in medicine. With the patient in a deep hypnotic state, the suggestion is made that he will be given a drink of whiskey and that this drink will immediately induce nausea, vomiting and abdominal pain. Water is used instead of an alcoholic beverage, but the hallucinatory effect is real. Posthypnotic suggestions are given to the effect that at any time he attempts to take a drink the same nausea, vomiting and abdominal pain will be produced. Posthypnotic suggestions last about a month and, when repeated, the desired effect may become permanent as has been previously pointed out by C. F. Patten and E. R. Kellogg (*Duration of Posthypnotic Suggestion, J. Abn. Social Psychol.* 25:319, 1930; *J. Exper. Psychol.* 12:502, 1929).

The deleterious effects of alcohol on the nervous system and body are impressed on the patient while he is in the deep hypnotic trance.

These suggestions are periodically reinforced through the induction of repeated posthypnotic states, which can even be produced over the telephone, after previous conditioning.

However, hypnosis is only a means toward speeding up the treatment, not the treatment itself, but when combined with modern psychoanalytic skill and knowledge it can be a much more effective shortcut in the treatment of chronic alcoholism than the ones described by Lemere and by Miller.

Alcoholism is merely the symptom of an underlying emotional or psychologic disturbance. It is true, as Miller states, that an attempt must be made to discover any mental conflicts, inhibitions, frustrations or personality changes that the individual may have. This is speeded up by hypnoanalysis, which is a rapid form of psychoanalysis under hypnosis (Hadfield, *J. A. Functional Nerve Disease*, 1920; Karup, *F. Hypnoid. Handl. ugen, Ztschr. f. d. ges. Neurol. u. Psychiat.* 90:638, 1924; Taylor, W. S. *Behavior Under Hypnoanalysis, J. Abn. Psychol. & Soc. Psychol.* 18:107, 1923). A regression technique described by K. I. Platonow (*Experimental Age Regression, J. Exper. Psychol.* 9:190, 1933) is used. The patient is reverted to the age prior to the onset of his drinking and then slowly reorientated to the present. The development of harmful habit patterns, complexes and other mental problems will be found quickly. When the patient's consciousness is reeducated by intensive psychotherapy under hypnosis, many permanent cures may be effected readily.

WILLIAM S. KROGER, M.D., Chicago

TOXICITY OF HUMAN PLASMA

To the Editor—In the September 19 issue of *THE JOURNAL* in the last paragraph of the editorial on the toxicity of human plasma it is stated that "a negative skin test precludes the possibility of intravenous plasma shock." I consider this a rather dangerous statement and one with which my experiences and teachings do not agree.

In the search for allergic sensitivities one finds that all too frequently cutaneous tests are not a positive assurance that the substance tested for is, or is not, a sensitizing agent in that particular case. Thus one obtains positive tests, for example to ragweed on persons whose history reveals no exacerbations or an entire lack of symptoms during the ragweed pollinating season. In these cases one can frequently apply ragweed pollen to the nasal mucous membrane or to the eye with completely negative results. On the other hand, persons giving a history of such a sensitization will definitely show symptoms when ragweed is applied in this manner and will also show symptoms on the ingestion of certain foods without showing any cutaneous sensitivity at all. Even a passive transfer fails to elicit a positive test.

It has been my experience that tests for normal horse serum act in the manner indicated. I have seen cases of shock result in persons who showed a negative test to normal horse serum. I have also seen persons who showed a definite positive cutaneous test to normal horse serum who did not have any reaction after the administration of products containing horse serum.

I think you will find that it is the consensus among allergists that there is a large percentage of persons whom we term "skin insensitive."

This does not mean that I think the intradermal tests are not valuable. They most certainly are, but I do not think such a hard and fast statement as that contained in the editorial is justified.

F. C. METZGER, M.D., Tampa, Fla.
Associate member of the Society for the Study
of Asthma and Allied Conditions

"FORCED SPINAL DRAINAGE"

To the Editor—I should like to express a word of appreciation of the careful and fair editorial in your issue of September 26 on "Forced Spinal Drainage in Acute Poliomyelitis." The point which is made in the last paragraph is of particular significance since it is necessary to exercise caution in applying the results of the treatment of an intracellular virus to processes dependent on extracellular infectious agents.

At the same time I should also like to point out that the fundamental physicochemical aspects of the Retan technique are diametrically opposed to forced spinal drainage. The intravenous injection of hypotonic saline solution without concomitant free drainage of cerebrospinal fluid produces a generalized edema of the central nervous system. This is not lessened by giving the intravenous injections at intervals. The susceptibility of an edematous central nervous system to infection is no indication of the susceptibility of that same nervous system to infection during continuous formation and drainage of the cerebrospinal fluid. This limits the general significance of the experiments to which your editorial refers.

LAWRENCE S. KUBIE, M.D., New York

Minnesota June Report

The Minnesota State Board of Medical Examiners reports the written examination for medical licensure held at Minneapolis, June 16-18, 1942. The examination covered 12 subjects and included 60 questions. An average of 75 per cent was required to pass. Sixty candidates were examined, all of whom passed. Three physicians were licensed to practice medicine by reciprocity and 2 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad	Number Passed
College of Medical Evangelists		(1942) 2	2
Yale University School of Medicine		(1938)	1
George Washington University School of Medicine		(1941)	1
Northwestern University Medical School	(1941) 2	(1942) 2	4
Rush Medical College		(1938)	1
Indiana University School of Medicine		(1937)	1
University of Louisville School of Medicine		(1936)	1
Tulane University of Louisiana School of Medicine		(1939)	1

MEDICOLEGAL ABSTRACTS

Osteopathy Use of Drugs and Practice of Surgery Denied to Osteopaths—The defendant Moore, a licensed osteopath, was charged with practicing medicine and surgery without a license in that he "prescribed and recommended, for a fee, drugs and medicines found in and comprising a part of materia medica in at least two specific instances. The defendant Muecke, a licensed osteopath, was charged with practicing medicine and surgery without a license in that he performed surgical operations for the removal of tonsils in certain specific instances, used the title "physician and surgeon" in connection with his name and represented that he was engaged in the practice of medicine and surgery. Both defendants, by way of defense, alleged that they were duly licensed to practice osteopathy and that the doing and performing of the acts charged constituted the practice of osteopathy as taught and practiced in legally incorporated colleges of osteopathy of good repute. In each case the trial court sustained a motion to strike from the answer these allegations, and the defendants appealed to the Supreme Court of Kansas.

The issue in these cases was the same and they were argued together. Essentially, the court was presented with this question: Does a license authorizing the holder to practice osteopathy as taught in osteopathic schools confer the right to use drugs and to practice operative surgery? In answering this question, the Supreme Court reviewed its previous decisions involving the scope of osteopathy and well considered decisions in other jurisdictions and pointed out that all such decisions distinguish the practice of osteopathy from the practice of medicine and surgery. Referring particularly to the Kansas law, the court said that the words of a statute must be taken in the sense in which they were understood at the time the statute was enacted and that the effect of the words in the osteopathic act authorizing licentiates to practice "as taught and practiced in the legally incorporated colleges of osteopathy of good repute" was not to set at large the settled meaning of osteopathy and obliterate the distinction between the practice of osteopathy and the practice of medicine and surgery. Under the act, the examining and licensing board is authorized to grant certificates to practice osteopathy only to persons who have met certain requirements. Those who have not met these requirements and who have not graduated from an osteopathic school or college of good repute are not eligible to receive a certificate. The obvious purpose of the legislature, continued the court, was to exclude the unfit and thus protect the osteopathic profession as well as the public. The purpose was not to enlarge the meaning of osteopathy but to guard that profession from applicants who had graduated from schools of low standards that purported to teach osteopathy.

We have, the court said, set forth authoritative definitions of osteopathy. To be a reputable college of osteopathy within the meaning of the Kansas statute the course of study taught and practiced must conform to those definitions. The theory of the defendants that they may practice whatever might be taught in such schools cannot be sustained. To say that the scope of practice of an osteopath in Kansas is measured by what is or may be taught in osteopathic colleges of good repute would be the equivalent of saying that the law of Kansas fixing the boundary line between the practice of medicine and surgery and the practice of osteopathy must be determined by the shift in the subjects taught in an unknown number of colleges in an unknown number of states. The court could find no warrant for such a contention based on any proper construction of the statutes. Nor did the court agree with the contention that the proper construction of a statute is a question of fact for the jury, not a question of law for the court. If such a contention were true, the court pointed out, the law would be as chameleon hued as the various verdicts of successive juries.

The court concluded, therefore, that while the defendants were authorized to practice osteopathy they were not authorized to practice medicine and surgery, that the acts charged constituted the practice of medicine and surgery and that the trial court did not err in striking the defendants' answers, since those answers constituted a mere conclusion of law and were no defense to the acts charged. The court could find no authority in the Kansas law for the limited use of medicine and surgery contended for by the defendants and said that it was beyond the power of the court to write an exception into the statute, such an exception being a matter for the consideration of the legislature, not the courts. The order of the trial court in sustaining the motion to strike the answer concluded the Supreme Court, was not an appealable order and the appeal was dismissed—*State ex rel Wheat, Co. 113 v Moore and State ex rel Coburn, Co. 113 v Muecke* 117 P. (2d) 598 (Kan., 1941).

Malpractice Negligence of Osteopath in Treating Fracture of Humerus—The plaintiff, on Dec. 24, 1937, fell and fractured the upper part of his right humerus. He was taken to the Cleveland Osteopathic Hospital and there attended by the defendant, an osteopath. A roentgenogram was taken which showed the break in the arm, and a traction device, known as a Thomas splint, was attached to the arm. Four days later another roentgenogram was taken, which disclosed a juncture of the bone fragments. The following day the osteopath applied a so-called airplane type plaster cast to the broken arm, which entailed raising the arm to a wing position and the application of plaster to hold the arm in rigid fixation. However, the osteopath made no effort to set the broken bone because, as he stated, the patient's entire constitutional system was bad and that "further treatment along other lines" would be necessary before anything more could be done with the fracture. By the plaintiff's own testimony, however, it appeared that his physical condition was good at all times during his relationship with the osteopath. On December 30 the patient was discharged from the osteopathic hospital and told to return on January 18, at which time the cast would be removed and the arm placed in a sling. Further treatment of the arm was not given and fluoroscopic or roentgenographic examination was not made until January 12, when a roentgenogram taken on the order of the osteopath showed the ends of the fractured bone out of alignment and overlapping. It appears that at that time the osteopath was dismissed from the case and two days later the patient, at the direction of a nonsectarian physician, had other roentgenograms taken at another hospital. The physician then advised the plaintiff that an open operation would be necessary to secure a satisfactory union of the bone fragments. Whether that operation was ever performed the instant court decision does not make clear, but it does appear that the plaintiff suffered a substantial impairment in the use of his arm. The plaintiff subsequently brought suit against the osteopath for malpractice, alleging negligence and unskillfulness on the part of the osteopath principally in (1) so applying the Thomas splint as to cause unnecessary pain, (2) so applying the plaster cast as to cause the fractured portions of the right humerus to get out of alignment and (3) failing to make any observation or examination by roentgen rays to determine the position of the fractured bones after the attempt to reduce the fracture.

At the trial the patient called as a witness a nonsectarian physician who testified that the usual and common medical practice in the reduction and treatment of fractured human bones is to tire out the muscles surrounding the break by placing a weighted extension on the arm for several days or until swelling has subsided and then, by manipulation and with the aid of a fluoroscope or by roentgenograms, to attempt to get the bone fragments end to end or in apposition, where upon a so-called airplane splint is ordinarily applied. This physician further testified that in his opinion the possibility of getting a meeting of the ends of the fractured bones in the case of the plaintiff, had they been set by this usual form

of manipulation under the fluoroscope or roentgen rays, was very favorable and that the fracture could have been set so that the ends contacted each other. The trial court, however, refused to permit the physician to answer a question as to whether or not he would be able to state from his examination of the roentgenograms taken at the osteopathic hospital on December 28, which showed the bones in contact, and from those taken at the second hospital on January 14, which showed the bones not in contact, what had caused the separation of the point of contact of the bones. The trial court's refusal was on the ground that the answer called for a conclusion that the jury would have to draw rather than one that the witness could properly draw. The plaintiff excepted, stating for the purpose of the record that the witness, if permitted to answer, would have testified that when the arm was turned back to a position upright with the head, which the osteopath did on December 28 in applying the airplane splint, the contact of the two bones was separated and caused to sideslip. At the close of the patient's evidence the trial court rendered judgment in favor of the osteopath, which action was affirmed by the court of appeals, Cuyahoga County, and the patient appealed to the Supreme Court of Ohio.

The plaintiff contended that the trial court erred in refusing to permit the medical witness just referred to to answer the question noted. The authorities, said the Supreme Court, are practically agreed that roentgenograms, with the technical aspects of which the ordinary layman is not familiar, may be interpreted and explained to a jury by qualified expert witnesses. And, while nonexpert witnesses are not usually permitted to express an opinion as to the cause of an occurrence involving an ultimate fact issue, experts in the particular field of inquiry may do so in certain cases. As was said in 20 Am Jur 686

The general rule is that opinions as to the cause of a particular occurrence or accident given by witnesses possessing peculiar skill or knowledge—that is experts—are admissible where the subject matter is not one of common observation or knowledge or in other words where witnesses because of peculiar knowledge are competent to reach an intelligent conclusion and inexperienced persons are likely to prove incapable of forming a correct judgment without skilled assistance.

As illustrative of this rule the court referred to *Pedigo v Roseberry*, 340 Mo 724, 102 S W (2d) 600, a malpractice action in which the court held that subjects of litigation not within general experience and common knowledge require the testimony of experts in such subjects for "the establishment of the ultimate fact." As we view it, said the Supreme Court, the patient was entitled to the benefit of the nonsectarian physician's opinion in response to the question referred to as an aid in sustaining the burden imposed on him of establishing negligence on the part of the osteopath and of showing a causal connection between the negligence and the claimed impairment of the arm. Of course, on cross examination, the accuracy and correctness of the physician's conclusion could be tested and the osteopath would have had the right to introduce other expert testimony, if he could, in contradiction. Considering the patient's evidence as a whole in the light most favorable to his contention, excluding the proper testimony of the nonsectarian physician which was rejected by the trial court, it discloses a situation wherein there was a contact of the broken bone fragments on December 28, a loss of such contact in the process of applying the airplane type splint and no further attention whatever given to the fracture by the osteopath for a period of two weeks. Coupled with this is the opinion of the nonsectarian physician that the break was of such a nature that it could have been originally set with good results in the usual and ordinary way. The court believed that the patient had made out a prima facie case against the osteopath, which should have required the latter to proceed with his evidence, and that the trial court was in error in rendering a judgment in favor of the osteopath at the conclusion of the evidence presented by the patient. The judgment in favor of the osteopath was accordingly reversed and the cause was remanded to the trial court for further proceedings—*Hall v Nagel* 39 N E (2d) 612 (Ohio 1942).

Drunkenness Admissibility of Evidence of Blood Test—The defendant was found guilty of operating a motor vehicle on the public highway while intoxicated and appealed to the Supreme Court of Iowa.

The defendant had consented to a blood test to determine the amount of alcohol present in his blood but on appeal contended that the trial court had erred in overruling his objections to certain questions propounded to the expert who made the test. This expert testified that he had found 400 mg of alcohol per hundred cubic centimeters of blood and that a person with that much alcohol in his blood was intoxicated. He further testified, in response to a question, that 150 mg of alcohol per hundred cubic centimeters of blood has been accepted by physiologists as the point at which an individual loses enough control over his nervous reactions to indicate that he is intoxicated. Objection was made to both the question and the answer. The Supreme Court held that the witness was competent, that the information called for by the inquiry was a proper subject for expert testimony and that the question was not objectionable as calling for a conclusion of the witness. In substance, the witness said that his statement that a person is intoxicated if he has 150 mg or more of alcohol per hundred cubic centimeters of blood is an accepted scientific fact. Evidence was not introduced to the contrary and there was nothing in the record to show that the blood test given by the physician was not reliable and accurate on the question of intoxication.

The defendant called attention to the expert's testimony to the effect that it would be possible for a man to drink a quart of whisky in the course of four hours and not be intoxicated while another might drink only 2 ounces and lose control of his faculties, that a man is not intoxicated merely because he drank a quart of whisky. The expert explained, however, that the blood of a man who drank a quart of whisky would not necessarily show an alcoholic content of 400 mg, it would not necessarily show more alcohol than one who drank a pint because of various other factors. The test of intoxication is not the amount of liquor consumed but the amount of alcohol in the blood. This testimony, said the court, is reconcilable with the prior testimony of the witness that any man with 400 mg of alcohol in the blood is intoxicated.

The defendant also contended that an instruction given by the trial court authorized a conviction on the testimony of the expert without regard to any other evidence in the case. The Supreme Court held that this was not true. The evidence of the expert was admissible on the question of intoxication and was entitled to be considered by the jury. The trial court told the jury that it should take into consideration all of the testimony introduced in the case in determining the guilt or innocence of the defendant. Since the Supreme Court found no error, the judgment of conviction was sustained—*State v Haner*, 1 N W (2d) 91 (Iowa 1941).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Clinical Pathology, Baltimore

12 399-448 (Aug.) 1942

Prolonged Action of Histamine C. F. Code, Rochester, N. Y. and R. L. Varco Minneapolis—p. 225
Normal Human Arterial Oxygen Tension S. C. Cullen and Evelyn V. Cook, Iowa City—p. 238

Desoxycorticosterone Prophylaxis for Shock—Katz and his associates determined the prophylactic and therapeutic action of desoxycorticosterone on occlusion of the venous return from one limb of the dog, which usually results in massive edema of that limb, shock and death. Fifteen control dogs received no desoxycorticosterone, 11 primed dogs received an average of 25 mg. in divided doses during the twenty-four hours preceding the operation and 35 mg. during the following twenty-four hours, 3 unprimed dogs received an average of 40 mg. of the drug starting two hours after the operation and continued for twelve hours and 6 dogs received 10 mg. ten minutes to two and a half hours preoperatively and an average of 36 mg. during the following twelve hours. Of the control dogs 2 survived and the others died in shock within three and a half to twenty-one hours. Although the occluded limbs became cold and severely edematous, the primed dogs appeared normal, drank water and were in good condition. Two of these animals given a smaller quantity of the drug preoperatively died in shock in four and

a half and twenty-nine hours. One dog with distemper died in twelve hours from pulmonary edema. The blood pressure in the 8 dogs that survived remained unchanged or was slightly reduced. Hemoconcentration was evident during the first several postoperative hours but returned toward normal the following day, followed in some by a long period of hemodilution, which was coincident with a gradual return of the edematous leg to normal. Seven of the unprimed dogs died in shock, 1 died of pneumonia and 1 survived. Desoxycorticosterone may not be efficacious in other forms of shock. Desoxycorticosterone might operate in one or more ways: (1) by maintaining normal capillary permeability or by controlling fluid exchange between blood and tissues, (2) by altering and controlling the water balance, (3) by operating directly on the cardiovascular system or (4) by counteracting the release of a toxic agent from the edematous limb.

Amphetamine Sulfate and Polycythemia in Man—Davis and Harris observed the effect of daily administration of amphetamine sulfate on producing polycythemia in 6 healthy men. The erythrocytes were increased 12 to 15 per cent in 5 of the 6 men within one to two weeks after the drug had begun to be taken. Hemoglobin percentages were increased proportionately. Total leukocyte counts remained fairly constant. When the ingestion of the amphetamine was stopped the erythrocyte count returned to normal in six to fourteen days. The erythrocyte count of the sixth man remained constant, around six million. Blood pressure, particularly the diastolic (about 6 mm.), was increased uniformly one to four hours after the drug was ingested by 4 of the 6 men during the first few days of ingestion. In the man in whom polycythemia did not develop there also was no minor blood pressure response. The results are explained by assuming that amphetamine sulfate increases hemopoiesis by causing a local hypoxia of bone marrow through a diminution of the blood supply to this tissue.

Pleural Effusion and Ascites with Fibroma of Ovary—According to Ritvo, Meigs's syndrome should be considered in all obscure cases of fluid in the cavity of the chest. If the condition is recognized, a favorable prognosis can be given. With an incorrect diagnosis of malignant disease the patient is subjected to needless mental and physical suffering, to many tappings of the pleural and peritoneal cavities for recurrent formation of fluid and to radiation therapy. Why the fluid recurs is not understood. It is a transudate with a specific gravity of about 1.015. Tapping is without effect. Operative removal of the pelvic mass results in complete and permanent cure without further reaccumulation of fluid. Irradiation is not indicated. It appears that this condition is relatively common.

and that many unrecognized cases exist. The clinical manifestations are discussed and 2 instances of ovarian fibroma recently observed by the author are reported. The diagnosis of the condition of the first patient was confirmed by pathologic findings and the patient was completely cured by operation. The second patient, observed for three years, has typical roentgen and clinical changes, but she has refused surgical operation because of her advanced age, 70 years.

Radium for Hongkong Foot—Eighty-two patients with Hongkong foot, a common fungous disease in China, have been given radiation treatment by Vassiliadis. 2 mg tubes of radium were filtered through 1 mm of platinum and were applied with plaster on the skin at 1 cm distance for forty-eight hours. The dose delivered is large enough to cause cutaneous desquamation in fifteen to twenty days, with complete healing within a month. Success depends on the disinfection of socks by boiling and of shoes by formaldehyde powder. If the patient can afford it, new shoes are advised. Eighty patients were cured after one treatment and have remained so after two to five years. Two patients were advised to have a second treatment, and the 1 who took it was cured. The other did not take the second treatment because the condition no longer bothered him much. *Epidermophyton rubrum*, *Epidermophyton inguinale*, *Trichophyton interdigitale*, *Trichophyton pedis* and a few other species have been isolated from Hongkong foot.

Staphylococcic Pneumonia During Epidemic of Influenza—In the course of the epidemic of influenza which had occurred during the late fall and early winter of 1940-1941 had involved most sections of the United States, the Hawaiian Islands, Puerto Rico and probably many other areas and which had reached Boston late in December and persisted throughout January, there were encountered, according to Finland and his co-workers, 66 cases of complicating staphylococcic pneumonia. Predominantly the infection was due to influenza A virus. As for the pneumonia the predominant organism obtained from one or more cultures of sputum or from the lungs was *Staphylococcus aureus*. Symptoms suggesting pulmonary infection began on the same day as those of the influenza in about one third of the cases, within five days in another third of the cases and were delayed six days to three weeks in the rest. All the patients included in the report were 14 or more years of age. However, infants and children with the infection were treated in the hospital during this period, some of the infants died. Among the 66 adults there occurred 21 deaths predominantly of patients more than 60 but the fatalities in the acute fulminating infections occurred mostly in middle aged people. Actually the mortality probably was lower, as many more cases of influenza with pulmonary minimal signs might have been included had more complete bacteriologic studies been made. All but 6 patients were treated with one or more of the sulfonamides. Usually the dose was 1 Gm every four hours during most of the febrile stage and either 6 or 4 Gm daily for a few days thereafter. Treatment in the severe cases was continued for one to four weeks. In 4 of the 6 cases of empyema complete recovery under chemotherapy occurred after one or more thoracenteses and did not require surgical drainage. The occurrence of sterile pleural effusions in severe infection with recovery and

the low fatality in cases with positive blood cultures are further indications of the efficacy of the drug in these infections. The exact role of the staphylococcus was difficult to evaluate, but the high incidence of abscesses of the lung, of empyema and of bacteremia associated with pure cultures of staphylococcus is strong evidence that this organism played an important role in the pulmonary infection. The staphylococcic pulmonary infection may vary from simple tracheobronchitis with minimal pulmonary involvement to a fulminating acute and fatal hemorrhagic and edematous pneumonia or a chronic organizing pneumonia with bronchiectasis and multiple abscesses. A brief course of treatment with sulfadiazine or sulfathiazole is suggested for severe uncomplicated influenza when patients harbor many pathogenic staphylococci or hemolytic streptococci or when these organisms are known to be prevalent in a community.

Exophthalmos and Goiter—Exophthalmos occurs in diseases other than of the thyroid. Soley limits his discussion to that which occurs in certain diseases of the thyroid. One of the reasons for confusion as to the presence or absence of exophthalmos has been the failure of many clinicians to distinguish "stare," or retraction of the upper (and perhaps the lower) lid, from protrusion of the eyeball. Several other situations may give rise to a false impression of exophthalmos. Lid lag associated with unilateral ptosis of an upper eyelid and overaction of the contralateral levator palpebrae superioris causing lid lag in the opposite eye. Exophthalmos can be confirmed only by careful observation and by actual measurement with the Hertel exophthalmometer. The measurements of eyes of 65 normal persons, of 106 with toxic diffuse goiter, of 52 with toxic nodular goiter, of 55 with nontoxic nodular goiter and of 2 before and after unilateral paralysis of the cervical sympathetic ganglions are presented by the author. According to his studies, eyes of more than 50 per cent of patients with toxic diffuse goiter become measurably more prominent after subtotal thyroidectomy, they become less prominent in only a few. These observations are contrary to the opinion of most surgeons who have relied on clinical impressions as to the state of exophthalmos before and after treatment. Loss of the stare associated with hyperthyroidism does not necessarily mean a decrease in exophthalmos. The eyes of thyrotoxic patients treated by roentgen rays show less tendency to increase in prominence. Therefore for patients with hyperthyroidism in whom exophthalmos is severe, roentgen therapy is more desirable than surgical subtotal thyroidectomy. Treatment of these particular patients should be directed toward preventing malignant exophthalmos.

Vascular Phase of Chronic Diffuse Glomerulonephritis—Horn and his associates studied the vascular phase of 49 consecutive cases of chronic diffuse glomerulonephritis selected from 5,232 necropsies. Specimens were fixed in a 40 per cent solution of formaldehyde U. S. P., Kaiserling I solution or Jores solution. Sections of the kidneys, pancreas, adrenals, testes, myocardium and all other available organs were diligently examined. In accordance with the varied vascular picture the disease was divided into a slowly progressive and an accelerated phase, there being 14 cases of the former and 35 of the latter. The intimal fibrosis, elastosis of arteries and arteriolar hyalinization, which were characteristic vascular alterations in the slowly progressive group were observed also in others. A transitional group in addition exhibited cellular proliferation, foam cells and edema of the arterial intima, while in the advanced accelerated group an even more conspicuous cellular intimal proliferation of the arterial tree and necrosis of the arteriolar walls were present. In most cases the intensity of the clinical picture usually paralleled the anatomic vascular changes. Neuroretinitis, common in the transitional and the advanced accelerated group, was never observed in the slowly progressive group. It is concluded that arterial alterations both in the transitional and in the advanced accelerated cases of chronic diffuse glomerulonephritis represent the anatomic equivalents of malignant hypertension. This occurred more frequently than is suspected in chronic diffuse glomerulonephritis. The constancy of severe hypertension in a miscellaneous group of diseases with accelerated arterial changes is considered a potent etiologic force in their production. The clinical course of chronic diffuse glomerulonephritis may be influenced not only by the exacerbation of the inflammatory process but by

the height of the blood pressure. The occurrence of severe hypertension and neuroretinopathy in various disease entities vitiates the belief that these criteria may be of differential diagnostic import. The vascular lesions once established cause the renal process to advance and intensify the clinical picture.

Pyelonephritis and Hypertension—Shure correlates the incidence of hypertension (150 mm systolic and 95 diastolic) and pyelonephritis in 11,898 consecutive necropsies. To complete the study he also studied the records of patients with hydro-nephrosis, nephrolithiasis and horseshoe kidney. There were 290 patients with pyelonephritis, in 224 of whom the condition was bilateral. There were 130 females and 160 males. Of the 88 patients more than 60 years of age, 69 were men and 19 were women. The preponderance of males in the total number is made up mainly of those in the older age groups. It can almost be assumed from the figures that fewer women survive pyelonephritis. It is likely that young women die of the disease in the acute stage. The incidence of pregnancy in these women was not ascertained, but the great preponderance of the disease in women of childbearing age is significant. Forty-four and four tenths per cent of all the patients regardless of age, sex and race had an elevated blood pressure. From 28 per cent in those aged 30 or less the incidence rises in direct proportion to age until it reaches 63 per cent in those more than 60 years of age. Similarly, the incidence of renal vascular changes is completely parallel with that of hypertension. In small groups of patients with polycystic kidney, horseshoe kidney and complicated nephrolithiasis the respective incidence of hypertension was 46.15, 64.7 and 53.25 per cent. The increase of hypertension with age may possibly be explained by the frequency with which high blood pressure occurs in elderly persons even without renal damage and therefore pyelonephritis is not an important factor in the production of their hypertension and by the fact that the occurrence of a much greater incidence of hypertension in the older age groups is in complete accord with the concept that the time element (duration of the renal infection) is important in the evolution of the hypertension associated with pyelonephritis.

Pneumoencephalography and Behavior—From the outpatient and consulting service of the Yale Clinic of Child Development, Amatruda collected 53 children with cerebral pathologic changes in whom it was possible to correlate the findings of the developmental examination with those of pneumoencephalography. The cases fell into the following classification: congenital malformations and aplasias, cerebral degenerative disease, epilepsy, hydrocephalus, cerebral injury, postmeningitis and postencephalitis. In the group are 11 patients whose development has proceeded normally in spite of indisputable roentgen evidence of cortical atrophy. 1 child recovered from meningitis (organism unknown), 2 have a communicating hydrocephalus and 8 are epileptic. Pneumoencephalography is a major procedure and should not be done if a simpler procedure will suffice. The usefulness of pneumoencephalography in many

pediatric conditions is not denied, but its limitations need reaffirmation. It is invaluable in locating intracranial tumors and in establishing the obstructive nature of a hydrocephalus. It is useful in the diagnosis of congenital cerebral malformations. It establishes an anatomic diagnosis. It does not picture the functional capacity of the cerebrum except when this capacity can be inferred from structural defects. Dilatation of the ventricles and widened cerebral sulci do not necessarily indicate any alteration in cerebral function or any diminution in developmental potentialities. In pediatric conditions involving developmental factors the developmental examination of behavior status measures function. Depending on the complicating factors, it also indicates the future capacities for growth and development. Behavior is the final criterion of the functional integrity of the central nervous system.

Salicylate Prophylaxis in Rheumatic Fever—The prophylactic value of acetylsalicylic acid was investigated by Coburn and Moore in 47 rheumatic children living in overcrowded tenements of New York City and exposed to the prevalent respiratory infections. The data are for a two year study. The subjects under observation were requested to report at the onset of pharyngitis, when salicylate therapy was instituted and throat cultures were obtained. In the cultures contained the hemolytic streptococcus group A, prophylaxis was continued for four weeks. The daily dosage was 4 to 6 Gm, depending on the size of the patient. If the cultures contained a respiratory pathogen other than the hemolytic streptococcus, salicylates were discontinued and the patients omitted from the study (in none of this group did rheumatic fever develop). Patients who contracted streptococcal pharyngitis and failed to report during phase I were observed as a control group. All but 1 of the 47 quiescent rheumatic subjects treated with sodium salicylate following hemolytic streptococcal pharyngitis escaped clinical manifestations of rheumatic fever. It was possible that prophylaxis in this boy had not been carried out as advised. Fifteen patients in the group had a brief asymptomatic rise in the erythrocyte sedimentation rate within a few days after prophylaxis was discontinued, however symptoms or signs of rheumatic activity did not develop in any of them. The expected occurred in the untreated control patients in 57 of 139 who contracted pharyngitis, rheumatic fever developed. In the untreated patients the antistreptolysin curves were like those which follow hemolytic streptococcus infections. Likewise typical antistreptolysin titer curves developed in the treated patients, about one half of them showed a late rise similar to that described in rheumatic fever. Statistical treatment of the data indicates that the failure of rheumatic fever to develop after salicylate prophylaxis following streptococcal pharyngitis is significant.

Bacteriologic and Chemotherapeutic Studies in Acute Diarrhea—The results of therapy with sulfathiazole and sulfaguanidine in acute diarrhea are reported by Halpern, who cared for 63 such children. 39 were less than 1, 20 between 1 and 2 and 4 between 2 and 5 years of age. During the child's hospitalization at least three stools were obtained for microscopic examination and culture. For culture studies SS agar was the best medium. The diagnosis in 47 was bacillary dysentery and in 16 nonspecific diarrhea. Of the 47, 23 were given sulfathiazole orally, an initial dose of $\frac{1}{2}$ grain (0.032 Gm) per pound of body weight was followed by 1 grain (0.065 Gm) per pound for each twenty-four hours divided into six equal doses. Sulfathiazole was usually discontinued twenty-four hours after the stools were normal. There was no evidence of toxicity. The results were good in all. The temperature dropped to normal within twenty-four to thirty-six hours, and the toxicity disappeared. Usually the stools were of good consistency and normal in number in five days. Sulfaguanidine was administered to 13, the first 5 received the same dose as that described for sulfathiazole and 8 an initial dose of $\frac{3}{4}$ grain (0.05 Gm) per pound of body weight, followed by a maintenance dose of $2\frac{1}{2}$ grains (0.16 Gm) for twenty-four hours divided into six equal doses. There were no unfavorable reactions. The course of the disease was similar to that following sulfathiazole therapy. Stools were normal in five and four-tenths days. Several children with severe secondary infection responded well to sulfaguanidine. Any concurrent infection improved as the diarrhea

ceased. Eleven mildly or moderately ill children received no specific therapy. Their temperature (100 to 101 F) remained elevated for several days, and fluids parenterally were necessary for a longer time than in those receiving chemotherapy. Stools were usually normal in six and three tenths days. There were no complications.

Treatment of Influenzal Meningitis—During the year ended September 1941, Scully and Menten treated 9 patients suffering with influenzal meningitis, 5 recovered completely. All were treated with type B anti-influenzal rabbit serum and a sulfonamide drug, and some also received the sodium salt of hydroxyethylapocupreine hydrochloride intrathecally. The death of 1 of the 4 patients who lived for more than four days after treatment was begun was due to drug nephritis and not to the meningitis. An associated mastoiditis, present in 5 of the patients, unfavorably influenced the patient's chance of recovery, especially if mastoidectomy was delayed. The anti-influenzal rabbit serum improved the prognosis. The meningeal irritation which followed the intrathecal use of the serum, indicated by a prompt increase in the cerebrospinal fluid cell count, raised the question as to whether intraspinal injection is justifiable or whether the intravenous route may not be preferable. Intrathecal use may be conducive to the further formation of fibrinous exudate in the pia arachnoid. In patients who readily responded favorably to the serum the spinal fluid became culturally negative in four to six days. However, fever sometimes persisted for six to fifteen days after serum therapy was instituted. A recurrence of symptoms after a period of quiescence should immediately suggest an unresolved focus of infection, especially in the mastoid or middle ear. An associated mastoiditis was apparently the precipitating factor in the death of 3 of the patients, and a grave complication in 2 who recovered. The low diffusibility of sulfathiazole and the fact that crystals of it may appear in the kidney would indicate preference for sulfanilamide and sulfapyridine. The appreciable reduction of the cerebrospinal fluid cell count following the use of either of them in the absence of serum indicates that they may be a valuable adjunct to serum treatment. Their use in conjunction with serum has not materially lessened hospitalization or convalescence. The bacteriostatic value of the sodium salt of hydroxyethylapocupreine hydrochloride intrathecally in 4 patients was problematic.

Abdominal Pain of Urologic Origin in Children—For the clinical background of abdominal pain of urologic origin, Campbell used the records of 213 children personally given a complete urologic examination in whom abdominal pain was the chief symptom on admission to the hospital. In more than half acute or subacute urinary infection was suspected or was discovered after an early examination. Yet in 14 the original diagnosis was appendicitis, nearly always "chronic," and in 13 others appendectomy had previously been performed but the pain persisted and the child was again brought to the hospital. In some children the cause of the pain remained uncertain even after extensive urologic, gastroenterologic, laboratory examination and, in a few, laparotomy. For the greater part the pains were the result of gradual or rapid distention of the collecting part of the urinary tract above a point of obstruction. Pain also resulted from swelling of the kidney within its dense and relatively inelastic capsule, the renal swelling may be due to acute inflammation, trauma (including stone), obstruction or tumor or it may develop more slowly when mild ureteral

obstruction exists. But all the urologic lesions which cause abdominal pain are predominantly obstructive and may be situated anywhere between the renal calyx and the urethral meatus. Except in an emergency it is advisable to correct the urologic disease before exploratory laparotomy is undertaken, as the first consideration will often render the second unnecessary.

Typhoid Due to Atypical Strain of Eberthella—During the last five years Harrell and Poston have encountered at Duke Hospital 5 cases of typhoid due to an atypical strain of Eberthella. One patient had previously been given typhoid vaccine but was not protected against the infecting strain. Although the disease was caused by an atypical strain, many clinical features of classic typhoid were present: stupor or mental dulness, bradycardia, long convalescence and complications (intestinal hemorrhage, infarction of the spleen, thrombophlebitis, pyelitis, furunculosis with abscess formation, pneumonia and recrudescence of the fever) were numerous. All the patients recovered. The organism was cultivated from the blood only and was never recovered from the stools, urine, bile or sputum. It was often difficult to demonstrate the organisms in the blood stream. Numerous cultures by various technics in 1 case were sterile, until cultures were made during the early part of a chill. As agglutinins developed for the atypical strain, the titer usually rose to a high level. The immune specificity was further indicated by the fact that transient cross agglutinins developed in only 1 case for *Salmonella paratyphi* or *Salmonella schottmuelleri* (paratyphoid A and B). These agglutinins were not due to the presence of Vi antigen. Treatment consisted of the usual supportive measures. Four of the patients lived in North Carolina and 1 in the District of Columbia.

Increase of Pulmonary Tuberculosis in Glasgow—

A study in 1941 of the increased incidence of tuberculosis in Glasgow revealed that it mainly involved males from 15 to 45 and females from 15 to 35. The rise was attributed to war conditions such as long hours, overwork, strain and curtailed rest. Laidlaw and Macfarlane's present study compares the returns for 1941 with those of 1940 and 1938-1939. It considers the data of a detailed investigation into the occupations and working hours of the first 1,600 confirmed cases of pulmonary tuberculosis notified during 1941. The number of notified cases among the young adults remains high, but the rate of increase during 1941 has slowed considerably. On the other hand there has been revealed a very real increase in both sexes of less than 15 and in males of more than 45. The increase in the young group is partly accounted for by an increased proportion of home contacts. The contention that overwork and long hours are playing a major part in the increase since the war is supported by the fact that little increase has occurred among the commercial and professional classes, whose hours of work alone remain within reasonable limits. Whereas less than 20 per cent of the commercial class exceed the recommended maximum hours of work, 67 per cent of the workers in heavy industries and 40 per cent in the medium heavy industries are working in excess of these standards. In the domestic class inquiry shows that nearly 40 per cent of housewives notified during 1941 were engaged in part time war work in addition to their household duties.

Pholedrine and Neosynephrin in Raising Blood Pressure—Elmes and Jefferson compared the effect of four sympathomimetic compounds, under standard conditions, in animals with a depressed blood pressure. The compounds were ephedrine hydrochloride, pholedrine sulfate, neosynephrin hydrochloride and phedracin hydrochloride. Ephedrine and pholedrine caused the most prolonged rise in blood pressure, the response to the first dose of each substance lasted for about forty-five minutes. The response to phedracin lasted for twenty-five minutes and the effect of neosynephrin for fifteen minutes. The duration of the blood pressure response to subsequent doses of ephedrine were rapidly and progressively diminished. The

response to pholedrine over the first four injections showed little change, and the response to neosynephrin remained constant throughout. Ephedrine and pholedrine act predominantly on the heart, whereas phedracin acts on the blood vessels and neosynephrin on both the heart and the vessels. Ephedrine and pholedrine cause an increase in heart rate, neosynephrin does not. A regular vasoconstriction is produced by neosynephrin and phedracin. An effect was not always to be seen with ephedrine and pholedrine. These results are of use in determining the possibility of substituting these substances for epinephrine in local anesthesia. Ephedrine, pholedrine or phedracin were not of value, but anesthesia could be prolonged with neosynephrin to within 25 per cent of the duration resulting with epinephrine.

Middle Meningeal Hemorrhage in Children—Lanigan reports 3 cases of bleeding from the middle meningeal artery without initial concussion and with a long latent period before symptoms ensued. In each the injury was apparently trivial, associated with momentary dizziness but no amnesia. The cases demonstrate the necessity of closely watching any child whose head has been injured. In 2 irritability and vomiting occurred six and two hours respectively after the accident. One was struck by a ball and 1 fell from a moving bus. These symptoms and dilatation of the pupil should be regarded as an 'alert'. These phenomena may indicate the onset of compression of the brain in cases in which there has been no concussion. After definite concussion these symptoms usually indicate a step toward recovery.

Sulfanilamide for Smallpox—Wilkinson observed that the toxic phase in 103 patients with smallpox was not influenced by sulfanilamide, 6 Gm in twenty-four hours, but that the focal phase was modified in some unvaccinated patients. The normal evolution of the lesions appeared arrested at the vesiculopustular stage and the secondary or focal fever was decreased or suppressed. The septic complications which occur so frequently in the focal phase were profoundly influenced by the drug, that is, the fatality rate among these patients was reduced.

- *Medullary Transfusion in Blood Diseases L Sanchez Yllades and H del Castillo—p 283
Roentgen Therapy in Dermatologic Diseases R Gomez Iarias—p 289
*New Method for Diagnosis of Valvular Insufficiency of Veins of Legs M Lopez Esnaurrizar—p 300

Bone Marrow Transfusion in Blood Diseases—Sanchez Yllades and del Castillo used in 15 cases the bone marrow of normal donors, which was obtained by aspiration, and injected it into the sternum of the patients. The injections were administered daily in a dose varying from 2 to 6 cc for each injection up to a total number which varied between one and four injections. The therapy failed in agranulocytosis, pancytopenia, subacute lymphoblastic leukemia and pernicious anemia of pregnancy. The results were good in hemohistioblastic purpura (after splenectomy), endotheliosis purpura, anemia following roentgen irradiations in chronic myeloid leukemia, pernicious anemia, macrocytic anemia and sprue.

Diagnosis of Valvular Insufficiency of Veins of Legs—Lopez Esnaurrizar made the observation that the oscilometric index in the legs of patients with large varicose veins and varicose ulcers and insufficient circulation is very much increased. He had noted that the oscillations are extensive when the patient is standing moderate when he is lying down in any posture and smallest in the dorsorecumbent position with the limb in flexion at a straight angle. The oscillations diminish or disappear when the limb is loosely constricted but reappear when constriction is removed with the same amplitude as that which was present before the limb was constricted. The oscillations are not synchronous with the arterial diastole, they are presystolic or arterial systolic. The author concludes that venous blood causes pulsation of varicose veins when the valves of the femoral vein are insufficient. An extensive oscilometric index in the legs of patients with diminished circulation in the lower extremities is of value in the diagnosis of valvular insufficiency of the femoral vein in cases of superficial varicose veins and also in the diagnosis of occult varicose veins with valvular insufficiency of veins.

Mortality in Antisyphilitic Arsenotherapy—Chana C first reports 12 fatalities from routine arsenotherapy in syphilis. Arsenical dermatitis was the most frequent cause of death being responsible for 6 of the fatalities. The majority of these patients presented acute pyogenic and gangrenous processes. Yellow atrophy of the liver was responsible for only 2 deaths. Apparently, in Chile this condition does not play the important part ascribed to it by American authors. Most types of jaundice caused by neoarsphenamine have a favorable prognosis in Chile. This may be due to the drug employed and to the lower fat content in the diet of the Chilean population. Jaundice is more frequent with the use of neoarsphenamine than with arsphenamine. Among the blood dyscrasias agranulocytosis is the most frequent. Etcheverry observed 27 cases of which 5 were fatal. The cause of death was sepsis, general complications or hemorrhages. The same author also observed 9 cases of aplastic anemia, of which 5 were fatal. Of Chana's 12 fatalities 2 were due to blood dyscrasias. Two other deaths were due to hemorrhagic encephalitis. As is indicated by observations in the United States, cerebral symptoms are rare in arsenotherapy of syphilis. Shock or acute renal syndrome were not observed in author's cases. The so called massive treatment has been used in Chile since 1938. Some employ the continuous infusion of neoarsphenamine or arsenoxide and others employ multiple daily injections. After directing atten-

tion to the high incidence of syphilis in Chile, the author says that the massive treatment has so far been employed in 1,300 cases, of which 14 were fatal. Hemorrhagic encephalopathy was the cause of all the 14 fatalities except 2 that is its incidence was 1 in 108 cases. Considering the fact that in the course of ordinary arsenotherapy the incidence of this disorder is only 1 in 27,400 (according to American statistics), massive therapy has increased the incidence of fatal hemorrhagic encephalopathy 253 times. These figures consider only the fatal accidents, but there are also grave complications which are not necessarily fatal, the author observed in one month two serious cerebral complications which were not fatal. In addition there are the polyneuritic phenomena, which although not fatal, often have an extremely slow recovery. They are comparatively frequent with the use of neoarsphenamine. The other 2 fatal accidents were due to necrotizing nephrosis a direct result of massive arsenotherapy. Choice of preparation is important in massive arsenotherapy. Arsenoxide is tolerated much better than neoarsphenamine. There were only 8 deaths among 936 patients treated with arsenoxide and 6 among 357 treated with neoarsphenamine. The massive form of treatment is advisable for the contagious cases which are resistant to the routine form of treatment.

*Clinical and Experimental Investigations on Regeneration Capacity in Epiphyseal Zone of Long Tubular Bones F Becker—p 488

Regenerative Capacity of Epiphysis of Long Bones—Becker applies the term epiphyseal cicatrix to the epiphyseal suture or synchondrosis disk. Clinical observations disclosed that fractures in the region of the epiphyseal cicatrix have a particularly favorable regenerative capacity. Pseudarthrosis is practically unknown in this region, it does not occur even after faulty treatment. The period of consolidation is extraordinarily short. Especially instructive are some types of fractures of the head of the radius when the zone of the epiphyseal cicatrix is preserved intensive regeneration takes place, but if it has been eliminated the regeneration is faulty. Fragments which contain parts of the epiphyseal cicatrix remain viable and may grow. Experiences in resection of the knee joint corroborate the good regenerative capacity of the epiphyseal cicatrix, the preservation of this zone, particularly of its peripheral portions seems to accelerate bone consolidation. The most convincing proof that the epiphyseal cicatrix is highly important in bone regeneration is furnished by observations in the post-traumatic collateral bone transformation. Roentgenologic studies on numerous unselected fractures disclosed in the zone of the epiphyseal cicatrix a sharply defined area of lesser density. The assumption of a zone of great regenerative potency seems the most probable explanation. The fact that malignant growths prefer the region of the epiphyseal cleft or cicatrix is another factor which speaks for the great regenerative capacity of this zone. Experimental investigations corroborate the clinical observations. Osseous articular portions regenerate in an anatomically ideal manner when the zone of the epiphyseal cicatrix is preserved, but slowly with deformity and incompletely when this zone is eliminated. When fragments of bone are transplanted into the adjoining musculature they usually remain viable if they contain parts of the epiphyseal cicatrix, but they become necrotic or are absorbed when they are taken from the diaphysis. Clinical and experimental observations leave no doubt that the epiphyseal cicatrix possesses a great regenerative capacity, which is latent under physiologic conditions but which becomes manifest under pathologic stimulation as in fracture, collateral transformation tumor development and the like. The question arises whether the epiphyseal cicatrix has the importance of a superimposed center of bone regeneration in the pertaining bone whether it is a 'field' or organization in Spemann's meaning of that term. Clinical and experimental factors, although they do not definitely prove the existence of such a field of organization in the zone of the epiphyseal cleft or cicatrix indicate this strongly.

Book Notices

Handbook on Amputations. Publication authorized by the Council on Physical Therapy. Reprinted from *The Journal of the American Medical Association*. Fabrikoid. Price 75 cents. Pp 82 with illustrations. Chicago: American Medical Association 1942.

This book is a fruit of the joint efforts of the Council on Physical Therapy of the American Medical Association and a committee from the Association of Limb Manufacturers of America to synthesize the points of view of surgeons, physical therapists and limb makers for the benefit of the patient. Its eleven chapters originally appeared serially in *THE JOURNAL* and are here brought together. The chapters deal with psychologic and physiologic principles in amputations, general principles governing all amputations, sites of election for amputation, amputations in diabetes and peripheral vascular disease, amputation in congenital and chronic disabilities, physical therapy in amputations, interrelationships of the artificial limb manufacturer, the surgeon and the patient, the manufacture of artificial limbs and rehabilitation. These subjects are developed and discussed in a brief and practical but authoritative manner. The illustrations are line drawings that picture well the points they are intended to illustrate. The work is authoritative to a high degree as it represents the combined efforts of leaders in the surgical, physical therapeutic and manufacturing fields pooling their knowledge for the benefit of the patient. It is unique in that the points of view of all concerned are brought together in a unified whole and demonstrates again the value of organized medicine acting as the coordinator of diverse specialties to teach and to standardize methods and procedures. Amputations of the extremities are common and are too often performed without thought of future function in terms of artificial limbs. Now that war has brought new causes for which amputations may be necessary this small book assumes new interest and proportions. It can be read with profit by those performing such operations and by those working for restoration of lost function. To every surgeon in civil or military life who may be called on to amputate, the reading of the monograph should be obligatory, as it simplifies and illuminates surgical operations that once were its chief ornaments but which have become commonly an uninspired performance as the result of lack of interest fostered by infrequent demands. A renewed opportunity afforded by the war for wider experience should be met by knowledge derived from this small but authoritative manual.

Clinoplastic Operations on Stumps of the Upper Extremity. By Rudolph Nissen M.D. and Ernst Bergmann M.D. Cloth. Price \$3.75. Pp 88 with 96 illustrations. New York: Grune & Stratton 1942.

This volume is of special interest and importance at this time because of the war. The basis of the authors' experience rests on the material of the Sauerbruch Clinic in Vienna, where the authors formerly worked. They have made certain modifications of the technique and present only those procedures which have stood the test of time.

The book contains the history of cinetization of an amputation stump, which means the practical utilization of the potential power remaining in the muscles of the stump. The purpose of the operation is to utilize the residual muscle power to motivate an artificial limb and to reproduce as nearly as possible the efficiency of a normal limb. The opening or closing of the artificial hand is accomplished by flexion and extension of the elbow. The authors give credit to Vanghetti for originating the method. He was not a surgeon, but he taught his fellow countryman Ceci the technique. Ceci used the method on wounded soldiers from the Abyssinian campaign of 1897. Sauerbruch took up the work where Ceci left off and established the technique as it is now practiced. Numerous authorities have contributed to the development and improvement of the technique. Krukenberg devised a definite technique of plastic reconstruction of the stump of the lower arm. The cinetization was introduced throughout the world, in the United States especially, by H. H. Kessler.

The authors limit themselves to the operative technique of the Sauerbruch muscle-canal construction, which they consider to

be the method of choice. They discuss the physiologic and anatomic aspects of the subject, going deeply into the question of voluntary muscular movement and all its components. One of the most important of their deductions is that muscles running diagonally to the long muscles of the body should not be employed to furnish power.

The book contains some beautiful and instructive illustrations on the muscles of the upper extremity with indications as to the optimal locations for making the canals. There are many instructive cross sections, some in color. The choice locations for operation and the optimal dimensions are given. If the biceps muscle is not available the brachialis may be substituted. The selection of cases is clearly designated. Cases of double amputation are the most promising subjects for cinoplastics. The potential strength of a canalized muscle is surprisingly great. It is equally surprising to note that the sense of touch can be acquired to a remarkable degree. The proportion of the stump neuromas, stump ulcer and atrophy of stump muscles are discussed. The patient is taught routine phantom movements. The operative technique is given in detail. The three most important points are that (1) the canal should be short and wide and constructed at right angles to the direction of the muscle fibers, (2) the canal should pierce the muscles at a level which will leave two thirds of the thickness of the available muscle mass between it and the bone and (3) the internal suture line of the skin tube should be placed proximally so that it will not be subject to any tension or compression during contraction.

The authors enumerate specific instructions that are given patients before anesthesia. The technique of the skin flaps and the position of the intracutaneous sutures of the skin tube are described.

There are some beautiful colored pictures of the technique of canalization showing every step in the process. The authors illustrate their results by showing patients lifting a pail of water and pouring its contents into another pail, patients striking a match and lighting a cigaret, opening and closing their hand, writing on a blackboard with chalk and removing a handkerchief from their pockets. A full page letter written by a patient with an artificial limb is reproduced.

The mechanism and construction of the artificial limb is presented in full. The technique of the plastic operation is well described and illustrated. The Krukenberg operation is given in detail. This operation is a method or plastic revision of the muscles of a forearm stump consisting of a grasping apparatus on the style of a forceps. The ulna and radius are the respective limbs. This operation has the advantage of grasping terminals with voluntary movement which gives them the additional advantage of tactile sensation, thus obviating the need of an artificial limb. If desired, a prosthesis can be added to supply function of the fist and fingers. The technique is presented and well illustrated. Naturally the mechanical accomplishments of a person with a Krukenberg stump are less varied than the person with a Vanghetti stump and prosthesis.

The book is easy to read and to understand by those who have had experience in this highly specialized type of work.

Serology in Syphilis Control. Principles of Sensitivity and Specificity With an Appendix for Health Officers and Industrial Physicians. By Reuben L. Kahn M.S. D.Sc. Director of Clinical Laboratories and of Serologic Consultation Service, University of Michigan Hospital, Ann Arbor. Cloth. Price \$3.10. 206 Baltimore. Williams & Wilkins Company 1944.

This book is not intended to be a guide book on the technique of making serologic tests for syphilis. As stated in the preface, it is an amplification of six lectures delivered at the U. S. Navy and U. S. Army medical schools at Washington, D. C. in the spring of 1939, and of classroom lectures given at the University of Michigan to physicians taking courses in venereal disease control. The book deals with the principles of serology and gives a broad survey of the development of complement fixation and precipitation tests. It is a faithfully written history of the role of the laboratory in the diagnosis and treatment and control of syphilitic disease.

There are two questions which confront a physician when he receives a report from a laboratory on a test for syphilis. What is the "sensitivity" and what is the "specificity" of the

test or tests utilized by this particular laboratory? In other words does the test when positive indicate that the patient has syphilis? When negative, does it indicate that he is free of syphilis? In the case under treatment, does the onset of a negative reaction mean a proof of cure? These are the practical points that interest the clinician. Kalin has attempted to answer these questions in a truly scientific manner by a discussion of the mechanics of the tests, complement fixation or precipitation, by statistical analyses by a review of the factors which are basically the foundation stones of this serologic structure. Sensitivity and specificity, definitions, whether or not to aim at hundred per cent sensitivity in syphilis, the efforts to increase sensitivity in both complement fixation and precipitation tests, the place of the supersensitive test, the attempt to arrive at an equalization of various tests by the so called multiple test system, the rationale of quantitative serologic reactions, finally, chapters on the serology of syphilis control by the health officer and by the industrial physician these are the various chapter headings.

This is a new type of book on serology—a serious and unbiased attempt to aid in interpretation of laboratory facts or reports—reports which have often left a physician confused rather than enlightened by reference of his problem to the laboratory. It should be a definite means of helping to clear up the smoke screen left by one or multiple laboratory reports. It is written by a serologist whose name is well known as the author of the most popular and commonly used precipitation test.

Acute Injuries of the Head Their Diagnosis Treatment Complications and Sequels By G. F. Rowbotham, B.S., F.R.C.S., Neurological Surgeon, Royal Victoria Infirmary, Newcastle on Tyne. With a foreword by Norman M. Dott, M.B., Ch.B., F.R.C.S., Neurological Surgeon, Royal Infirmary, Edinburgh. Cloth. Price \$7.50. Pp. 298 with 124 illustrations. Baltimore: William Wood & Company, 1942.

This is one of the best books on the subject thus far written. The wide experience of this author, both in civil and in military life, enables him to speak authoritatively concerning the management of the acute brain injury.

He stresses the role played by the automobile as the causative factor of acute head injuries. Apparently the experience in England is comparable to our own. The numerous air raids and bombings which the English have undergone enable the author to present excellent descriptions concerning the mechanisms of closed compound and penetrating brain injuries.

Dr. Rowbotham stresses the importance of close observation and repeated neurologic examinations, the evaluation of each sign and symptom and the approximate diagnosis of the brain lesion as necessary guides to treatment. In addition to the neurologic findings he interprets the significance of pulse and respiratory rates and especially blood pressure findings.

He has classified his cases into three groups according to the state of disturbed consciousness and the depth of the unconsciousness. His explanations and interpretations of these various phenomena indicate a highly trained neurologic background.

Under treatment the author gives the greatest emphasis to spinal drainage and operative procedures. He feels that knowledge concerning the presence of subarachnoid bleeding and the spinal fluid pressure, as gaged by the manometer, are two of the most important guides concerning subsequent management. Therefore in the unconscious patient he recommends a spinal puncture after twelve hours, with removal of spinal fluid until the manometer reading has reached 50 mm. If the pressure is high he advocates repeating the spinal puncture as often as every four hours thus striving to keep the spinal fluid balance as near normal as possible. One has the impression that this author is one of the strongest advocates of spinal drainage in the management of acute brain injuries. He points out the radical attitude of certain authors concerning dehydration management and the opposition of other authors to any form of dehydration. He then states that he uses hypertonic, 50 per cent, sucrose solution and magnesium sulfate enemas for dehydrating purposes but to a point midway between that advocated by Temple Fay and the nihilist attitude of Jefferson. He feels that in cerebral edema dehydration assumes its greatest role but prefers to depend on spinal drainage when blood is present in the spinal fluid.

Rowbotham devotes a considerable portion of his book to operative treatment of acute head injuries. One gains the impression that he turns to subtemporal decompression per se or exploratory decompressions more frequently than do the majority of surgeons in this country. This is due probably to the nature of the war injuries he is now treating. We do not believe that in civil life such a high incidence of operation is necessary. His description of various operative measures for the correction of large bony defects in the skull following these injuries is definitely instructive and valuable. The book is well illustrated, especially in the chapters on pathology and operative technique.

Ambassadors in White The Story of American Tropical Medicine By Charles Morrow Wilson. Cloth. Price \$3.50. Pp. 372 with 42 illustrations. New York: Henry Holt & Company, 1942.

The subtitle of this book—The Story of American Tropical Medicine—is more correctly descriptive than the main title. The merits of this subject for popular consumption in fact have been greatly neglected. Now the whole field of tropical medicine is vitally important to the northern as well as to the southern American continent. The author, who perhaps may be best described as a roving reporter, writes this for the nonmedical public, but it contains much information which would surely be news to most physicians. In the preparation of this book the author has gone to unusual lengths in investigating his facts; it is exceptionally well documented, but the documentation is arranged so as not to interfere with the ease of reading. The author has given proper recognition in the story of yellow fever to the long neglected Carlos Finlay of Cuba. Chapters each are also given to the better known Walter Reed and Gorgas of Panama Canal fame. Dr. William E. Deeks of Canada and his part in Central American medical history again is less well recognized, but he also is given a chapter. The work of many other physicians and public health officials is discussed without, however, making the book read too much like a catalogue. Incidentally, in connection with the recent publicity over jaundice following the use of yellow fever vaccine, chapter 13 of this book mentions the fact that millions of doses of yellow fever vaccine have been supplied by the laboratories of this country. There are a few minor defects in style, especially in the first two chapters the word "ironically," for example, is overworked. There are four appendices the first being devoted to acknowledgments, the second is a general bibliography the third a chronological list of Latin American epidemics and the fourth a list of populations in Latin American countries. The book can be recommended for either professional or non-medical readers.

A Short History of Nautical Medicine By Louis H. Roddis, M.D., Captain, Medical Corps, United States Navy. Washington, D. C. [Reprinted from *Annals of Medical History* (Third Series Vol. III Nos. 3, 4 and 5, 1941).] Cloth. Pp. 359 with 13 illustrations. New York & London: Paul B. Hoeber, Inc., 1941.

This book includes two parts: a general history of maritime medicine in which some of the story of the United States Navy has been included and a series of biographies of the surgeon generals of the United States Navy. It is only the first part that is included in the present work. Chapters are provided on early nautical medicine, disease and disaster in the old sailing ships, the medical departments of naval vessels, the rise of naval hygiene, naval medicine in the United States Navy, hospitals for seamen and hospital ships, nautical medicine and the merchant marine, the uniforms and insignia of medical men afloat, and research in nautical medicine. The material has presumably appeared in large part in the *Annals of Medical History* and has been picked from that publication for inclusion in this book. It is therefore in an easily readable column, well illustrated, with large type and will be found a most enjoyable volume by any one who is at all interested in medical services in the Navy. The author writes with little embroidery but with a succinct factual style. His essay on research in nautical medicine presents a list of some forty subjects demanding more elucidation than is now available and indicating trends in research which should be exceedingly useful for those who are trying to make progress. The book concludes with a chronological table of accomplishments in naval medical history.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

MOSQUITO "BITES"

To the Editor—What is the nature of the substance instilled in one during a bite by a mosquito which is responsible for the itching and inflammatory reaction? What is the exact chemical structure of the compound?

Richard L. Fruin, M.D., Chicago

Lieutenant M. C. U. S. Navy

ANSWER—The nature of the substance inoculated by mosquitoes in the act of "biting" is a subject of considerable debate. The intensity of the reaction to the bite of these insects varies with the individual, and persons frequently exposed develop a species specific immunity. Extracts of mosquitoes (Benson, R. L. *Diagnosis and Treatment of Sensitization to Mosquitoes, J. Allergy* 8:47 [Nov.] 1936) and of fleas (Cherney, L. S., Wheeler, C. M. and Reed, A. C. *Flea Antigen in Prevention of Flea Bites, Am. J. Trop. Med.* 19:327 [July] 1939; McIvor, Barbara C. and Cherney, L. S. *Studies in Insect Bite Desensitization, ibid.* 21:3 [May] 1941) have been prepared and employed with considerable success in the immunization of individuals hypersensitive to the bites of these insects.

In 1911 Bruck (*Deutsche med. Wochenschr.* p. 1787) prepared a glycerin and chloroform extract of whole mosquitoes which he named culicin. This extract produced a reaction when inoculated into the skin similar to the bite of a mosquito. Bruck reported that the extract had hemolytic powers. Nuttall and Shipley (*J. Hyg.* 1901-1903) prepared saline extractions of the salivary glands of *Culex pipiens* and found that the extract neither prevented coagulation nor caused hemolysis. Schaudinn (*Abh. a. d. k. Gesellsch. Naturh.* 20:387, 1904) found that the so called sucking stomach (esophageal diverticulum) of the mosquito was emptied during feeding and that the contents produced a noticeable and characteristic irritating effect when introduced through an opening in the skin. Schaudinn was unable to reproduce a similar irritating effect by injecting extracts of salivary glands under the skin. He believed that the characteristic irritation of the mosquito bite was due to enzymes from commensal yeast cells present in the contents of the sucking stomach and inoculated as the mosquito sucked blood.

McKinley (E. B. *Salivary Gland Poison of Aedes aegypti, Proc. Soc. Exper. Biol. & Med.* 26:806 [June] 1929) working with *Aedes aegypti*, prepared saline extracts of the salivary glands and found that these extracts would produce the characteristic wheals in susceptible individuals. These extracts were not destroyed by freezing to -12 C for five hours or by heating in boiling water for ten minutes and did not produce hemolysis of human red cells or prevent coagulation. McKinley (E. B., Draper, W. F., Jr., and Baker, F. C. *Stability of Mosquito Venom in Vitro, ibid.* 41:168 [May] 1939) found that the extracts retained their potency after eight years' storage under refrigeration.

Although the composition of the toxic principle introduced by the mosquito while sucking blood is not known, it is believed to resemble closely bee venom, which is considered a combination of lecithin with basic radicals somewhat resembling sapotoxins and cantharidin.

STUTTERING

To the Editor—A boy aged 3 began to stammer following an acute respiratory illness several months ago. What is the etiology and prognosis? Should I try to prevent his stammering or ignore the condition thinking he will outgrow it?

M. D. Arizona

ANSWER—Stammering (stuttering) is a somatic manifestation of an emotional disorder based on a psychobiologic variation of the organism. As yet there is doubt as to the exact mechanism that underlies this variation, but evidence strongly suggests the presence of an inherited constitutional factor which predisposes to emotional instability and psychomotor disorganization in general and to stuttering speech in particular. However, a person's inherent psychosomatic deficiencies would not in themselves cause stuttering speech without some active precipitating

factor: shock, cumulative environmental pressure, radical change of environment or, as in the instance cited, acute or prolonged illness.

There are two stages in the development of stuttering, primary and secondary. The child under discussion is apparently in the primary stage. The chances of arresting the disorder are much greater in this first stage, before anxiety and inferiority feelings begin to develop and before conditioning has had time to operate. In the primary stage, therapy is largely a matter of slowing down the tempo of living and removing any exciting stimuli in the home environment, particularly the excitement and tensions generated by neurotic parents. Family quarrels, exciting games, rapid speech or other "nervous" reaction patterns on the part of parents or older children should be eliminated. The child should be kept in as good a physical condition as possible; he should have frequent periods of rest and relaxation, and fatigue should be avoided. Also, since the stuttering child demonstrates in general a lowered degree of psychomotor efficiency, especially in those functions requiring fine coordination, a certain amount of rhythmic work is recommended: games and simple exercises in time to music, marching to the beat of a toy drum, bouncing a ball in rhythm and the like. He should be encouraged to do everything, speaking included, slowly and easily. Games in which the whole family participates can be devised to inculcate the idea of slow, easy, rhythmic activity.

With regard to the stuttering symptom itself, the parents should avoid correcting the child's speech directly, since this may make him speech conscious and precipitate the second stage of the disorder. A tactful suggestion—Let's all try to talk slowly and easily, I don't hear so well today—will usually produce better results than making a child repeat a specific word or phrase with which he has had difficulty. The parents should also avoid the all too common habit of interrupting the child when he stutters, talking for him when he is having difficulty or suggesting some "tool"—taking a deep breath, for instance—to help him over the blockage. Such tactics serve only to rouse his awareness of his difficulty and to develop anxiety and feelings of inadequacy. If possible, the child should not be allowed to suspect that the physician or parent is concerned about his speech or that it is in any way abnormal. One should concentrate, rather, on his assets and strive to develop a confident, secure personality. This together with the elimination of tension and excitement in the home environment and the general slowing down of the child's reaction patterns will in most cases arrest the development of the disorder before it reaches the secondary stage. The important point to remember is that in the early stage of stuttering therapy should always be indirect and should enlist the cooperation of the entire family.

MORPHINE IN TREATMENT OF BURNS

To the Editor—Some confusion seems to exist regarding the use of morphine in the treatment of severe burns. Becker and Obermeyer's *Dermatology* page 248 states that the administration of morphine in severe burns is a mistake. For pharmacologically yet unexplained reasons morphine has a deleterious effect and considerably increases the mortality of severe burns as proved by statistics. The literature on the treatment of burns from the Medical Division of the U. S. Civilian Defense advocates morphine in large and repeated doses. Which is correct?

Harold O. Closson, M.D., Ashland, Ken.

ANSWER—The use of morphine in severe burns is still a controversial question. The statement in Becker and Obermeyer's book that the administration of morphine is a "mistake" does not, however, represent the majority opinion in this country at the present time. Weiderteld (*Arch. f. Dermat. u. Syph.* 61:33, 301, 1902) himself a dermatologist opposed its use as do several other German writers on the subject, including Hilsenfeldt (*Ergebn. d. Chir. u. Orthop.* 29:102, 1936).

The modern treatment of burns requires debridement and cleansing, and for this purpose some sort of analgesic is essential. It is to be granted that any analgesic increases the danger, but probably no more so than for any other operation on a sick patient. In the United States morphine is considered preferable to general anesthesia in early burn treatment and, to be effective, must be given in adequate doses. Careful observation of the patient during the first hour after the administration of morphine is essential and signs of anoxia or slowing of the respiratory rate should be a signal for prompt administration of oxygen. The recent recommendations of the United States Navy (*Bull. Am. Coll. Surg.* 27:111 [April] 1942) and of the National Research Council (*War Med.* 1:334 [March] 1942) advise an initial dosage of 1/2 gram (0.032 Gm.) of morphine for the average sized adult. Quarter gram (0.016 Gm.) repeat doses may be ordered as indicated.

The literature concerning the pros and cons of morphine administration in the treatment of burns is listed in extenso by Henry N Harkins (The Treatment of Burns, Springfield, Ill, Charles C Thomas, 1942)

TREATMENT OF EXCESSIVE HAIR ON LEGS

To the Editor—Many women are going without hose at the present time and are therefore concerned more than ever before with the growth of hair on the legs. Please advise whether it is better to shave or to use a depilatory or bleaching compound. Kindly give details of the procedure recommended including the formula or name of the preparation to be used.

Needham B Bateman MD Atlanta Ga

ANSWER—Whether to shave the legs with a razor or to use a depilatory is a question of personal preference. Neither is harmful if done correctly. A simple formula for a depilatory

	Gm or Cc
Fresh barium sulfide	80
Zinc oxide	
Starch	at 120

Mix and label "Moisten with water to make a paste." Apply this to the hairy surface and allow it to remain for about ten minutes. If there is a burning sensation before the ten minutes has elapsed, remove it sooner. Scrape off the paste and the hair with a smooth wooden blade and wash off the remaining paste.

An easier method is to buy one of the prepared depilatories and follow the directions adapted to that particular preparation.

According to Hair-Dyes and Hair-Dyeing Chemistry and Technique, by H Stanley Redgrove and J Bari Woolss (London, William Heinemann, 1939 p 134) hair may be bleached by washing, and drying the hair, then applying with absorbent cotton or a brush a mixture of 20 volume hydrogen peroxide and one twentieth of the amount of ammonia water 0880. This corresponds closely with the stronger ammonia water of the U S P. The authors warn against using too much ammonia, suggesting 1 to 30 in certain instances. The bleaching should take place in a few minutes. To bleach a whole head of hair takes from ten to forty minutes, and the short sparse hair on the legs should be decolorized much more quickly. Dry the legs by pressure with a towel. Ordinary 3 per cent peroxide will not do the work.

RAGWEED HAY FEVER

To the Editor—I am suffering from hay fever caused by ragweed. This was established in 1940 by a cutaneous test. Last year while I was using an extract prepared by an allergist containing common and giant ragweed 20 000 pollen units per cubic centimeter my nasal symptoms were negligible. (Preseasonal treatment was started in May.) This year I used Lederle's ragweed combined antigen in approximately the same dosage as last year but the symptoms at the onset of the season were much worse than last year and I could neither taste nor smell for about 2 weeks. The 1942 desensitization period was started in the middle of April and finished at the beginning of August with the planned maximal dose of 20 000 units. Severe nasal symptoms started around the middle of August. I continued to take 20 000 units of Lederle's ragweed combined antigen in one injection once weekly. The ragweed pollen count in St Louis (air distance from here approximately 87 miles) varied between 100 and 550 in twenty-four hours. At the beginning of September the dosage was split to 10 000 units twice weekly followed by considerable improvement of the nasal symptoms. There is now a moderate local reaction lasting for about 24 hours and it seems some increased nasal irritation following the injection. The ragweed count in St Louis during this month was mostly below 100. 1 Would it be advisable for me to take only 10 000 units once weekly during this season? 2 Is there any theory concerning the action of the pollen antigen in the treatment of allergic conditions which makes an adjustment of the weekly dosage during the season possible by observation of the individual patient and by the twenty four hour pollen count? 3 How many pollen units taken preseasonally are considered sufficient to produce a relative state of immunity against the offending pollen? 4 Judging by my symptoms do you think that there existed an incongruity in the standardization of the extract used in 1941 and 1942? What conclusions do you draw for the next year's treatment schedule?

MD Illinois

ANSWER—The experiences suffered by the inquirer are typical of those which occurred this season throughout the ragweed belt. The total amount of ragweed pollen in most communities was probably smaller this year than in 1941, but the onset of the hay fever season was extremely severe, and most of the pollen was thrown out into the air in the last two weeks of August. Labor Day, usually about the worst day of the season, was comparatively mild this year, and after Labor Day the season remained mild.

In answer to the questions: 1 Most men doing allergic work try to have their patients reach as high a dosage as possible just before the hay fever season begins, after which the dosage is usually reduced from one fourth to one third. Most allergists continue to give this reduced amount at intervals of approximately once or twice a week during the hay fever season.

After the season is over, the dosage is then gradually increased at intervals of every two weeks so that when the next hay fever season starts the patient has reached a higher dosage than he had the previous year. This method of treatment is strongly recommended. 2 While this method is correct in general there must necessarily be some variations, depending on the individual patient. For example, one who has no symptoms at all need not have a reduction of dosage. In one who has severe hay fever symptoms, it may be wise to reduce the dosage as much as 50 per cent. 3 No one knows how many pollen units taken pre-seasonally are sufficient to produce a relative state of "immunity" against the offending pollen. There is a wide difference of opinion on this point. Some men are content to give a top dosage of approximately 5,000 units, and others strive to reach 60,000 or even 100,000 units before the season starts. The consensus is, however, that the patient should be pushed up, with the proper precautions, to as high a dosage as he can tolerate. Those who can reach 50,000 to 60,000 units usually have but little hay fever, and if this amount can be continued or increased over a period of years there is a fair chance of more or less permanent immunity. 4 There was probably no incongruity in the extracts used in 1941 and 1942. It is suggested that the dosage should be increased as much as possible and that the plan outlined under 1 be followed.

PLASMA FOR TRANSFUSION AND FATE OF ERYTHROCYTES

To the Editor—I am interested in the problem presented by the technical aspects of making human plasma to be stored for emergency use. If you have any suggestions or bibliography, I would welcome such information. When plasma is being collected, the whole blood of the donor is taken. About 50 per cent of this total volume eventually becomes plasma and the cellular elements are thrown away. Is there any reason why a fairly simple technique could not be worked out to return the cellular elements (properly diluted in saline solution and the like) to the donor and thus (a) avoid this waste of cellular elements (b) permit the donor not to suffer the loss of the cells and (c) permit the donor to return much sooner to make further plasma donations, since there would be no loss of cellular elements? The physiologic advantages would seem to be desirable and certainly the psychologic aspect would be improved. People always think of red blood and if they knew that they were giving only the water in the blood the number of contributions would step up remarkably. Any comments you care to make would be of considerable assistance.

MD Massachusetts

ANSWER—The human plasma for use by the armed forces is prepared under a joint agreement by the American Red Cross and the National Research Council. Under this agreement all technical procedures are specified and approved by the National Research Council, the National Institute of Health and the representatives of the Army and Navy. By the terms of these specifications the blood is obtained from donors in centers provided by the Red Cross. The processing of the blood into plasma must be done in biologic laboratories operated under license from the National Institute of Health. Under this arrangement the whole blood is transported often many hundreds of miles, from the bleeding center to the processing plant. Were the red cells to be used to replace those removed so much handling and time would be required as to render the procedure impracticable. Much thought has been given to this problem, and attempts have been made to convert the waste erythrocytes into crystalline hemoglobin which could be returned to the donor to serve as a source for new hemoglobin production. This procedure has not been found to be satisfactory. It is doubtful whether the replacement of the removed cells would permit the donor to return much sooner to make further blood donations. The trauma to erythrocytes inevitable in the repeated handling involved in the separation of plasma would in all probability render these erythrocytes more fragile than normal. Were this the case they would tend to be destroyed in the circulation more rapidly than untraumatized cells. Adequate evidence is at hand to warrant the assumption that the breakdown products of such destroyed erythrocytes would serve as an ideal source of building stones for new hemoglobin. However, the rate of blood regeneration after a single 500 cc blood donation is so rapid in healthy persons that its acceleration by the return of removed erythrocytes appears to be not worth the expense and hazard involved.

The fact should be recalled that in the fiscal year July 1, 1942 to July 1, 1943 three million five hundred thousand donations will be made for the armed forces. This rate requires the utmost speed and efficiency in the operation of the donor service. To add a second procedure which would involve the introduction into the vascular system of a labile biologic product would be uneconomical and more serious distinctly dangerous.

TABES WITH BEGINNING OPTIC ATROPHY

To the Editor—A man aged 65 with tabes dorsalis and moderately advanced Charcot's joint is having rapidly increasing contracture of his visual fields. The ophthalmologist states that in an Argyll Robertson pupil there is some narrowing and tortuosity of the vessels and that the disks are more white and shiny than normal but well defined. A recent ophthalmologic examination excludes the presence of any evidence of optic atrophy but discloses the presence of bitemporal hemianopsia. The blood pressure is 190 systolic 110 diastolic and the heart is normal except for a moderate enlargement. The tones are not clear and there is an occasional premature beat. The urine contains a slight trace of albumin and there are a few hyaline and granular casts. All blood serologic reactions for many years have been persistently negative but spinal fluid taken in January 1942 was reported positive. Considering the man's age and general physical status I should be disposed to refrain from all intensive therapy were it not for the fact that the constriction of his visual field is proceeding fairly rapidly. I should appreciate word as to the treatment that should be used in this case. Should dependence be put entirely on iodides or are arsenic and other heavy metals perhaps even trypanamide indicated?

M D Illinois

ANSWER—Best results will be achieved in cases of beginning optic atrophy in connection with tabes dorsalis through the use of fever therapy. However, for a patient of this age and with a blood pressure of 190/110 (noting particularly the diastolic pressure and the fact that the urine contains a slight trace of albumin with a few hyaline and granular casts) it is questionable whether fever therapy could be used. A more conservative procedure would be potassium iodide internally in 0.5 Gm doses three times a day. Intravenous injections of sulfurphenamine 40 mg for a series of ten treatments may be employed followed by intramuscular injections of iodobismutol 2 cc twice a week for a series of ten weeks. After this the arsenical and bismuth therapy may be repeated.

Naturally it will be necessary to watch a patient like this closely, particularly the kidney and cardiac condition. The outlook is poor in a situation of this sort.

LYMPHEDEMA AFTER SPRAINED ANKLE

To the Editor—I have seen occasional cases of sprained ankles in which the swelling was out of proportion to the pain and if persisted for years. X-ray examination in each case was negative for osseous pathologic changes. Can you offer any suggestions as to further study or treatment?

M D District of Columbia

ANSWER—If ligaments are overstretched until some of the fibers are actually torn and the position of the foot following, this injury is not well maintained in a neutral or overcorrected position, the fibers will heal with an excess of scar tissue and with an actual elongation of the ligaments. Such ligaments are then too lax to maintain good stability. There is a tendency constantly for the ankle to wobble and for strain of weight to be thrown against the over-relaxed ligaments in walking, or even in standing. Such ligaments and the tissues surrounding them become edematous. This is a lymphedema. The condition may be prevented by adequate immobilization followed by a period of exercises and heat and massage by a good physical therapist. This helps to accelerate circulation of lymph and of blood. The chronic cases do not respond well to any type of treatment. Support by an elastic stocking or bandage for several months is sometimes helpful.

PLASTIC INDURATION OF CORPORA CAVERNOSA

To the Editor—A man aged 65 with advanced arthritis deformans and chronic valvular disease complains of rather frequent erections and that his penis bends acutely upward or dorsally and that therefore the sexual act has become impossible. He wants me to cut the dorsal ligament. He has no other symptoms of prostatic enlargement such as nocturia or frequency. His prostate is of normal size and his urine is normal.

Joseph O Rude MD Juneau Alaska

ANSWER—The clinical description given is typical of plastic induration of the corpora cavernosa, more generally known as fibrous plaques of the corpora cavernosa and described sometimes as Peyronie's disease. This disease is characterized by fibrous nodules in the sheath of the corpora cavernosa or in the septum between these two bodies. This fibrosis encroaches on the corporal contents at times and disturbs the elasticity of the tissue affected and makes for a chordee in the direction of the lesion. This chordee may be lateral, either side, or dorsal or a combination of dorsal and lateral.

This disease has no known etiologic factor, although it has been known to be associated with gouty tendencies or chronic arthritis such as is present in this case and probably represents some factor concerned with the primary infectious disease. Surgical removals have been failures in most instances because it not only recurs but will have a superimposed surgical scar.

There have been a few reports of improvement by the use of applications of radium and more recently by high voltage roent-

gen therapy. The writer has seen no important benefit from any type of irradiation or medication, although possibly massage of the lesion over a sound has a tendency to prevent progress of the lesion and, at times, may reduce the symptom of local pain which sometimes occurs during an erection.

PONTOCAINE HYDROCHLORIDE AND CORONARY THROMBOSIS

To the Editor—For fourteen years I have been using pontocaine hydrochloride solution 0.5 per cent and 2 per cent for local anesthesia in the nose and larynx. I have never seen any disadvantages. Recently I applied pontocaine hydrochloride 2 per cent to get an anesthesia of the vocal cord for the removal of a common polyp from a healthy man aged 47. After the administration of about 1 cc of the standard solution without epinephrine or ephedrine the patient showed the typical signs of pontocaine intoxication such as nausea, vomiting, sweating, choreic movements, dilated pupils, cyanosis and rapid pulse. After one hour he recovered completely. For the following three days he didn't feel so well but couldn't give any specific complaints. The later course was absolutely uneventful. Fourteen days after the incident the patient was suddenly taken ill and showed all the symptoms and signs of a coronary thrombosis. Do you think that there is any relation between the pontocaine intoxication and the coronary condition?

M D New York

ANSWER—It is highly improbable that the pontocaine intoxication induced or even favored the occurrence of the acute coronary thrombosis in this case. In the first place the drug itself can be excreted and in the second place the time interval if given correctly, is too great. It is true that certain accidents which cause a severe reaction with considerable circulatory depression as in the case of peripheral vascular shock due to pulmonary embolism, can and occasionally do result in acute myocardial infarction with or without actual coronary occlusion, almost always superimposed on a considerable degree of coronary atherosclerosis with narrowed lumen. Such heart lesions, however, develop rapidly, either during the reaction to the accident itself or within a few hours or a day or two after ward. An interval of two weeks, as in this case, strongly suggests that the acute coronary thrombosis was a coincidence and would have taken place anyway even without the pontocaine intoxication. It is, of course, barely possible that the coronary occlusion might have occurred painlessly during the day or two immediately after the administration of the anesthetic, to become manifest only fourteen days later but the history makes this highly unlikely.

CONVEX FINGER NAILS WITH NUTRITIONAL ANEMIA

To the Editor—During my stay in Nassau General Hospital I found a peculiar malformation of the finger and toe nails of patients suffering from a nutritional hypochromic macrocytic anemia. The nails present a convex surface both longitudinally and transversely resembling the convex aspect of a spoon and just the opposite of koilonychia. They remind one of club fingers. From these they differ in that the pulps of the fingers or toes are not distended and the phalanges taper normally. This is best seen on the volar aspect. I wonder if the condition is known and mentioned in the literature.

M D Bahamas

ANSWER—As far as can be determined this type of nail has not been reported to occur specifically in hypochromic macrocytic anemia (Pardo-Castello, *A Diseases of the Nails*, Springfield Ill and Baltimore Charles C Thomas, 1941; Cleveland White, personal communication). Such an anemia may be caused by a combination of deficiencies including iron plus the pernicious anemia principle protein or vitamins. Hardwick (*Arch Dis Childhood* 14:279 [Dec] 1939) reported clubbing of the finger nails of 2 children with celiac disease. In this condition there is frequently a calcium deficiency.

The convexity of the finger nails noted is probably related to the nutritional deficiency.

LABORED RESPIRATION AND DROPPING MANDIBLE

To the Editor—I have noticed many times in deeply comatose patients a dropping of the lower jaw which greatly impedes the already labored respiration. By simply lifting the chin one relieves the obstruction to the respiration. The same is true in inhalation anesthesia. Why does air passage at once? The same is true in deep coma cause obstruction of the air passage and what is the mechanism of relief when the jaw is lifted?

M D Iowa

ANSWER—With passive relaxation of muscles in general under the conditions described the jaw muscles allow the mandible to sink dorsocaudally. This in turn relaxes the supports of the pharynx and larynx attached to the mandible. The larynx tilts backward and partially closes the glottis by the pressure of the base of the tongue on the epiglottis. Lifting the mandible removes the mechanical obstruction and permits free play of the epiglottis.

THE PREVENTION OF TOXEMIA OF PREGNANCY

N J EASTMAN, MD
AND
JOHN WHITRIDGE JR, MD
BALTIMORE

It is well known that both the incidence and the maternal mortality of eclampsia in the United States are declining. During the past decade the incidence of the disease at the Johns Hopkins Hospital, as shown in the accompanying table, has been about one fourth of that observed during the first two decades of the century and less than half that seen during the twenties. At the same time a gratifying decrease in the maternal mortality of eclampsia has occurred, the death rate having fallen from over 20 per cent in the early years of the century to 5 per cent during the past decade.

Not only has the incidence of eclampsia in the general clinic population decreased, but today the disease accounts for a much smaller percentage of our total number of cases of toxemia than it did even fifteen years ago. As may be seen in chart 1, cases of eclampsia constituted 11.8 per cent of all toxemia admissions in 1927 but only 2.1 per cent in 1940 and 1.3 per cent in 1941. Meanwhile, however, the incidence of toxemias of pregnancy in general among the clinic population has increased, indeed, if all types of toxemia are grouped together under the designation total toxemias, it may be seen in chart 1 that this group represented only 9.6 of all obstetric admissions in 1927, but during recent years it has constituted between 16 and 20 per cent of all admissions. While several factors may be responsible for this increase in total toxemias, two conclusions would seem inescapable from the data presented: (1) Something has happened which has reduced dramatically the incidence of eclampsia and (2) in current practice in an overwhelming majority of cases of toxemia of pregnancy the condition is not eclampsia but a nonconvulsive type of toxemia.

Concerning the dramatic reduction in the incidence of eclampsia, it should be noted that this circumstance is not peculiar to our clinic but holds true, as we have learned from conversations with obstetricians the country over, in the same degree wherever good antepartum care is available. Contrariwise, in certain regions of the country where such care is not available the incidence of eclampsia, we have reason to believe, has remained much the same. Further extension of antepartum care promises therefore a still further diminution in the incidence of the disease.

It is true that this salutary reduction in the incidence of eclampsia is the result of good antepartum care, it would seem appropriate to ask what specific measures have been responsible for this effect. Stated briefly, the primary factor responsible for this decrease in the incidence of eclampsia has been the early detection and appropriate treatment of the prodromal stage of the disease, namely preeclampsia. In order to achieve this end, vigorous adherence to the following program is obligatory.

1 Expectant mothers must visit their physician or an antepartum clinic not later than the second missed menstrual period and make visits thereafter as follows: during the first five months every four weeks; during the sixth, seventh and eighth months every two or three weeks; and during the last month every week.

2 Since the earliest warning signal of impending eclampsia is usually suddenly developing hypertension, the importance of frequent and regular blood pressure readings during pregnancy cannot be emphasized too often. The absolute blood pressure reading is probably of less significance than the relationship it bears to previous estimations and to the age of the patient. For example, a rise from 110/70 to 135/85 in a young woman is a more urgent danger signal than a rise from 135/85 to 150/90 in a patient of 35. We have seen a number of girls of 15 and 16 with eclampsia whose blood pressure never exceeded 135 systolic and 90 diastolic, but the normal, basal pressure of these young women was in the neighborhood of 105/65. Similarly, in China, where the blood pressure of every one averages 10 or 15 points lower than in this country, eclampsia with readings of 130 systolic and 85 diastolic is not uncommon.

3 The next most constant sign of preeclampsia is sudden, excessive gain in weight. Sudden gains of more than 2 pounds (0.9 Kg) a week should be viewed with suspicion and gains of more than 3 pounds (1.4 Kg) with alarm. Weight increases of the latter magnitude call for more frequent blood pressure examinations than previously recommended and if these readings are also abnormal, hospitalization with intensive treatment is often indicated. If cases of preeclampsia are studied from the point of view of fluid intake and output, it is at once apparent that these sudden gains in weight are due entirely to an accumulation of water in the tissues. Such weight gains, in other words, represent latent edema and almost always precede the visible face and finger edema which is so characteristic of the advanced stages of the disease. From what has been said, it is obvious that a pair of scales is essential equipment for good antepartum care.

4 The sudden appearance of albumin in the urine with or without other findings or symptoms should always be regarded as a sign of impending eclampsia.

Usually it develops later than the hypertension and gain in weight and for this very reason must be regarded as a serious omen when superimposed on these other two findings

5 But the very essence of eclampsia is the lightning-like fulminance with which it often strikes. Although the aforementioned physical signs of preeclampsia

Eclampsia Incidence and Maternal Mortality at Johns Hopkins Hospital 1896-1941 (478 Cases in 44 722 Admissions)

Period	Admissions	Cases	Incidence per Cent	Deaths	Mortality per Cent
1896-1905	2 442	52	2.1	12	23.0
1906-1915	5 183	93	1.8	19	20.4
1916-1922	4 595	107	2.3	17	15.9
1923-1930	11 770	127	1.1	13	10.2
1931-1941	20 053	99	0.5	5	5.0

usually give the physician ample time to institute preventive treatment, it sometimes happens that these alterations develop between visits to the office or clinic, even though they are only a week apart. For this reason it is imperative that all expectant mothers be informed both verbally and by some form of printed slip or booklet in regard to certain danger signals which they themselves may recognize. As far as the toxemias of pregnancy are concerned, the following demand immediate report to the doctor: (1) severe, continuous headache, (2) swelling of the face or fingers, (3) dimness or blurring of vision, (4) persistent vomiting, (5) decrease in the amount of urine excreted and (6) epigastric pain (a late symptom).

In the face of the warnings of developing toxemia, as mentioned, the physician's first duty is to make arrangements for frequent blood pressure readings at least once a week and in unusually alarming cases two or three times a week. During this period of preliminary observation the following routine is recommended: 1. A salt poor diet, that is, one in which no salt is added either in the kitchen or at the table. 2. Restricted activities, complete rest in bed being desirable in most cases. 3. Saline catharsis at the outset of the treatment and repeated twice weekly. 4. Maintenance of fluid intake at about 3,000 cc daily, that is, eight to ten glasses of water. 5. Sedation such as is given by phenobarbital, the dosage being dependent on the severity of the condition, if convulsions are actually imminent, heavy sedation with paraldehyde may be desirable. 6. With regard to the protein content of the diet, this is a debated subject, but in our opinion the balance of evidence lies in favor of those who permit a full diet of meat provided the meat is not salty.

If a satisfactory response to treatment is obtained either in the home or in the hospital, the pregnancy may be allowed to proceed to term, but with the patient under careful observation at frequent intervals. Temporary improvement is often followed by sudden acute aggravations.

Often, however, no amount of therapy serves to check the onward progress of the hypertension and accompanying signs. In such a situation the realization of two facts becomes of utmost importance: 1. Such patients are very likely to develop eclampsia with its accompanying risk to mother and child. 2. Permanent damage to the vascular system with permanent hypertension is likely to be a late result if the process is allowed to continue indefinitely even though eclampsia

is avoided. Many recent studies indicate that the duration of the toxemia is more important in this respect than any other factor.

Termination of the pregnancy, therefore, becomes the treatment of choice under such circumstances. Two means of ending pregnancy are available on the one hand, induction of labor followed by vaginal delivery and, on the other, cesarean section. The decision as to which of these two courses is preferable may be a very difficult one to make and depends on a number of factors: the duration of the pregnancy, the condition of the cervix, the parity of the patient and the level of the fetal head in the pelvis. Time does not permit any detailed consideration of this phase of our subject, but several brief considerations can be given: 1. In a patient near term, with the cervix at least 1 to 2 cm dilated, soft and thin and the head well in the pelvis, artificial rupture of the membranes will almost always bring about prompt labor and delivery. 2. In a patient three or more weeks from term and the cervix long, closed and firm, particularly in the primigravida, elective cesarean section offers the mother and child the better chance. 3. In the large group falling between these two extremes, all factors must be carefully weighed. The severity and suddenness of appearance of the toxemia, the probability of eclampsia, the condition of the cervix and the probable time interval before delivery can be effected from below must all be taken into consideration in making this decision. One must balance on the other hand the added mortality from cesarean section if performed against the mortality to be expected from eclampsia if it develops.

It is along lines such as these, then, that countless numbers of cases of eclampsia have been prevented in recent years and the incidence of the disease reduced. During the past few decades, as we have already noted,

Chart 1—Eclampsia constitutes a smaller proportion of total toxemia than it did fifteen years ago.

the death rate from eclampsia has also been brought to a fraction of what it was at the turn of the century. It may be seen from chart 2 that the falling maternal mortality rate from eclampsia at the Johns Hopkins Hospital is directly associated with the type of treatment given. Prior to 1916 therapy was governed by the belief that immediate delivery was imperative. Consequently, accouchement force, manual dilation of the cervix and cesarean section were the favored pro-

cedures of that day, with the tragic results that are shown, a mortality rate between 20 and 23 per cent. Between 1917 and 1922 an effort was made to be more conservative, but if the condition was at all severe or if sedative treatment was unsuccessful in stopping the convulsions immediately, the fortitude of the attendants failed and radical operative delivery was effected. Nevertheless a substantial improvement resulted with

Chart 2—The decreasing maternal mortality of eclampsia as the result of conservative treatment

a death rate around 16 per cent. Between 1923 and 1930 a modified Stronganoff regimen was followed, and under no circumstances was operative delivery employed except for occasional outlet forceps. This reduced the mortality rate to 10.2 per cent. During the past decade the death rate has diminished still further as the result, possibly, of greater individualization of cases, more liberal use of hypertonic dextrose solution intravenously and digitalization.

These figures speak for themselves and leave no doubt that radical operative treatment is deadly to eclamptic patients. To be sure, it may seem illogical to condemn cesarean section in eclampsia when we recommended it in certain cases of severe preeclampsia. However, experience shows that once a patient has had a convulsion she is an extremely poor operative risk and remains so as long as she is in the active convulsive stage. Consequently sedatives, darkness and quiet constitute our best allies in the treatment of eclampsia. As for the best sedative drug to use, opinion varies, but during recent years we have been employing paraldehyde with satisfactory results. A dose of 30 cc by rectum is administered on admission, followed by doses of 15 to 20 cc as may be necessary to control the convulsion.

Having reviewed certain aspects of eclampsia, let us turn to some other phases of the toxemias of pregnancy. We have shown that, whereas the incidence of eclampsia was decreasing, the sum total frequency of all types of toxemia in our clinic population was increasing. This increase is due in large measure to the fact that gravid women with chronic hypertensive processes are becoming more and more of a problem. In chart 3 we have superimposed the graph of our incidence of chronic hypertensive vascular disease during the past fifteen years over the graph showing our incidence of eclampsia and total toxemia. It is apparent that chronic hypertension has made up a rather constant percentage of our total toxemias during this period, and, since the latter have increased, the conclusion is obvious that chronic hypertensive vascular disease is also being seen more frequently. During the past five years it has been observed about ten times more frequently than eclampsia.

Chronic hypertensive vascular disease used to be called "chronic nephritis" and is often referred to by internists as "essential hypertension", but, by whatever name it is designated, the clinical characteristics are plain enough. The patient is usually in the upper age groups, in the thirties or late twenties, she is usually a multipara. Before the seventh month of gestation is reached, often during the first half of the process, the patient shows a pronounced elevation of blood pressure. The hypertension may have existed prior to pregnancy, if so, the early months of gestation bring about an increase in both systolic and diastolic pressure. Albuminuria and abnormalities of the urinary sediment may be absent, the renal function is often normal, edema is minimal or lacking and the patient has no complaints other than occasional headaches. But the hypertension persists usually at a fairly constant level. At this time only one other positive finding may be noted, and that is narrowing and tortuosity of the retinal vessels, in other words a retinal arteriolar sclerosis. The pregnancy may proceed to the expected date of confinement, or, as commonly occurs the fetus may die in utero and be expelled prematurely. In either event the child is underweight, while the placenta shows an unusual number of infarcts, often red infarcts. After delivery there may be a slight recession in the blood pressure, but usually it remains indefinitely at a figure only slightly below that observed during pregnancy. Each subsequent pregnancy adds its increment to the hypertension, and, as a rule, the exacerbation in the blood pressure occurs earlier and earlier in each succeeding pregnancy. In most of these patients the hypertension and the arteriolar sclerosis persist for years without other findings, some show a more malignant course. Sooner or later, however, all manifest certain organic changes. The largest group, probably, show renal alterations, albuminuria and a rather rapid

Chart 3—Chronic hypertensive vascular disease has constituted a rather constant percentage of the total toxemias over the past fifteen years

diminution in renal function. Once the latter sets in, the course is a short one and death ensues, often within a few months, from uremia. Another class of these hypertensive patients, possibly almost as large as the renal group, manifest cardiac changes, hypertrophy, occasional attacks of decompensation and finally fatal heart failure. In a third group, characterized usually by severe hypertension, death results from apoplexy.

At the present time large numbers of women with chronic hypertension are becoming pregnant and dying each year. The increasingly important role played by chronic hypertensive vascular disease in maternal mortality is clearly shown in chart 4. Here it may be seen that in our experience chronic hypertension is superseding eclampsia as a cause of death in childbearing and has been responsible for almost 80 per cent of our toxemic deaths in the past decade. Indeed, during the past quarter of a century the relative positions of eclampsia and chronic hypertensive vascular disease have become just reversed.

The problem presented by chronic hypertension in pregnancy is quite different from that of eclampsia and preeclampsia. In such patients we cannot prevent the occurrence of hypertension because they already had hypertension when conception took place, they already had at that time a sclerosed, unelastic arteriolar tree, and it is understandable that the 50 per cent increase in minute output of the heart which pregnancy imposes will place a severe burden on their vascular system. In the face of this chronic process and this load imposed by pregnancy, one can do but little in such cases to relieve the hypertension. But one can aid the patient

3 In the large intervening group of patients with blood pressure in the neighborhood of 150 to 160 systolic, without albumin in the urine or with a small amount only and with very slight evidence of damage elsewhere in the body, the question is a difficult one. The duration of the pregnancy, the parity of the patient, the case with which pregnancy could be terminated and the patient's desire for the child must all be considered. It is the physician's duty, however, to warn the patient of the risks accompanying the continuation of pregnancy under such circumstances.

If, for any of these reasons, immediate termination of pregnancy becomes necessary, what procedure is to be followed? In deciding between the abdominal and the vaginal route a point of primary importance is whether or not sterilization is to be performed along with interruption. As a general rule any chronic disease making interruption of pregnancy advisable is also an indication to terminate the childbearing career. The following summary may help as a guide.

If sterilization is not to be done: (1) If the pregnancy is of less than fourteen weeks' duration, therapeutic abortion from below is recommended, (2) if the pregnancy is between fourteen and thirty weeks' duration, abdominal hysterotomy is advised, (3) if the child is viable, or possibly viable, the problem arises of allowing the pregnancy to continue until the child has a reasonable chance of survival. This will depend on the severity of the process and duration of the pregnancy. Whenever possible under these circumstances delivery from below should be carried out. Cesarean section should be reserved for severe cases in which conditions are such as to make rupture of the membranes unwise, usually the presence of a firm, long, tightly closed cervix.

If sterilization is to be performed: (1) If the pregnancy is of less than thirty weeks' duration, abdominal hysterotomy with tubal sterilization or abdominal hysterectomy is recommended, (2) if the pregnancy is of more than thirty weeks' duration pelvic delivery if possible is advised followed by sterilization in the early puerperium. Cesarean section should be performed not merely because sterilization is to be carried out but only when difficulty with pelvic delivery can be anticipated.

There is one further type of patient frequently encountered, namely the patient who shows mild but definite hypertension during one or more pregnancies but whose blood pressure is normal between pregnancies. This patient has the so-called repeat toxemia of pregnancy, and the evidence is gradually accumulating to prove that such patients if allowed to go through successive pregnancies eventually develop chronic vascular damage. Their childbearing careers should be limited by one means or another.

Our weapons, then, in dealing with chronic hypertension in association with pregnancy are (1) education of the patient with emphasis on the prevention of pregnancy, (2) interruption of pregnancy if necessary and (3) sterilization at the time of delivery or after delivery. Not only is the hypertensive patient an extremely poor obstetric risk, but each additional pregnancy appreciably shortens her life expectancy. The problem she presents is becoming one of the most frequent, as it is certainly one of the most serious, in modern obstetrics.

Chart 4—Over the past quarter of a century the position of eclampsia and that of chronic hypertensive disease in this clinic have become just reversed as causes of maternal death.

by helping to prevent pregnancy. Hence the problem is largely one of preventive medicine in the sense that pregnancies should either be avoided altogether or should be limited.

Given a pregnant patient with chronic hypertension, what is the proper treatment? The answer depends on (1) the severity of the process, i. e. the blood pressure level and the degree of renal or cardiac damage, (2) the duration of the pregnancy when the patient is first observed and (3) the willingness of the patient and her husband to follow the physician's advice. Within rough limits the following types of treatment are recommended.

1 When the process is severe, that is, in the presence of blood pressure in excess of 170 systolic, albuminuria, reduced renal function, lowered cardiac reserve or fresh retinal hemorrhages, there should be immediate termination of the pregnancy whatever the stage of pregnancy.

2 If the process is mild, with blood pressure of 140 to 145 systolic, no albumin, normal renal function and normal eyegrounds, the pregnancy may be allowed to continue with the patient under close observation for signs of impending trouble.

INCIDENCE OF MALIGNANCY IN PREPYLORIC ULCERS

B R KIRKLIN, MD

AND

WILLIAM C MACCARTY JR, MD

Fellow in Radiology the Mayo Foundation

ROCHESTER, MINN

The incidence of malignancy in gastric ulcers near the pylorus, long assumed to be disproportionately higher than that of ulcers situated elsewhere in the stomach has become in recent years an open question. In 1925 Orator¹ found in a survey of material at von Eiselsberg's clinic that 30 per cent of prepyloric ulcers were carcinomatous whereas only 2 per cent of ulcers on the lesser curvature in the median portion of the stomach were carcinomatous, and malignancy of duodenal ulcer almost never was observed. In 1929 Haudek² gave his influential endorsement to Orator's conclusions. Later one of us (B R K),³ who often had heard Carnian comment on the frequent occurrence of malignancy in prepyloric ulcers, expressed the opinion that ulcers near the pylorus are more likely to be carcinomatous than those on or near the lesser curvature well removed from the pylorus. References could be multiplied easily to show that for many years similar views were held commonly, and this consensus was strengthened in 1933 by Hampton⁴ when he reported that all prepyloric ulcerations observed at the Massachusetts General Hospital during a period of three years proved to be carcinomatous. However, a few observers had begun to doubt the view of the majority, or at least to suspect that confusion had arisen from failure to agree on definitions of terms or from differing bases of study. Then in 1936, from material comparable in extent with that of Hampton, Singleton⁵ concluded that in any given case of roentgenologically demonstrable ulcer within 1 inch (2.5 cm) of the pyloric sphincter the mathematical probabilities are at least two to one, and more likely four to one, that it is a benign ulcer. Thus the issue has become definitely joined, and in order

to contribute data that may aid in solving it we have reviewed a series of cases seen at the Mayo Clinic.

As a preliminary to the projected survey, all gastric lesions diagnosed roentgenologically and proved surgically and pathologically at the clinic during a single presumably typical year (1939) were canvassed to discover the proportion of prepyloric to other gastric lesions and the proportion of benign to malignant prepyloric lesions. In all there were 373 cases, the pyloric segment was the site of involvement in 112 (30 per cent) and 93 (83 per cent) of these proved to be malignant as against only 19 that were benign.

MATERIAL

Since a roentgenologic approach to the investigation seemed most expedient, it was determined to review all cases in which the roentgenologic diagnosis at the clinic was prepyloric ulcer, ulcerating or obstructing lesion at the pylorus or duodenal ulcer, during the five year period 1937 to 1941 inclusive. Cases in which carcinoma had been diagnosed definitely as such were not included. Records of all the cases were reviewed and only those proved surgically and pathologically were accepted for study. Fluoroscopic notes and roentgenograms were gone over in each instance. Especial care was taken to determine the situation of the lesions and only those that were confined to the 3 cm of stomach immediately proximal to the pyloric ring or that appeared to have originated in this segment were considered to be prepyloric. In this connection it is noteworthy that both Hampton and Singleton confined their study to lesions in the distal 2.5 cm of the stomach. Our series comprises 190 cases.

ROENTGENOLOGIC DATA

Taking separately the classifications according to diagnosis, there were 47 cases in which the examiner discerned a niche-producing lesion which appeared to be purely ulcerous, without tumefaction or other indication of malignancy, and the roentgenologic diagnosis accordingly was ulcer, implying that the ulcer probably was benign, although malignancy could not be excluded positively. At operation and pathologic examination a benign prepyloric ulcer was found in 34 instances and a malignant prepyloric ulcer in 5 instances. In the remaining 8 cases the lesion proved to be ulcerating carcinoma in 3 and ulcer at the base of the duodenum in 5.

A diagnosis of ulcerating lesion at the pylorus was made in 26 instances. In 9 a benign prepyloric ulcer was found, malignant ulcer in 2, ulcerating carcinoma in 10, duodenal ulcer near the pylorus in 4 and carcinoma of the pancreas in 1. Although the examiner

stimulation) vagus fibers innervate only the surface epithelial cells, fibers of intermediate irritability excite the zymogenic chief cells or peptic cells or possibly only the mucoid or neck chief cells, which may also secrete some pepsin, and the least irritable fibers excite the parietal cells. Such a precise distinction between separate nerve fibers may apply only under special experimental conditions, but the more general conclusion that each individual type of gland cells is innervated by a distinct group of nerve fibers¹⁰ appears to be justified. It may be further presumed that normal or pathologic reflexes may act selectively through one or another group of nerve fibers and thus influence the secretion of mucus, pepsin or hydrochloric acid separately.

Braxer¹¹ found that stimulation of the splanchnic nerves induced secretion of mucus with slight peptic activity, chiefly from the pyloric portion of the stomach. He expressed the opinion that the secretion came from the pyloric glands rather than from the surface epithelium. The work of Vollborth and Kudryavtzev¹² indicates that the splanchnics send a few fibers also to the parietal and chief cells of the gastric glands.

CHEMICAL EXCITATORY STIMULI

The best known chemical stimulus for gastric secretion is histamine. The secretion resulting from histamine stimulation contains a relatively large proportion of hydrochloric acid and a relatively small amount of pepsin and mucus.¹³ Histamine therefore acts as a powerful stimulus for the parietal cells. Since 'histamine juice' regularly exhibits some peptic activity,¹⁴ however slight histamine may also stimulate but less powerfully other secretory elements of the gastric glands. This is not a necessary conclusion since the pepsin present undoubtedly results in some cases from continuation of the stimulated secretion with resting secretion, especially in human beings, or it may be washed out of the gastric glands by the free flow of hydrochloric acid,¹⁵ or it may, as suggested by Linn and Mä,¹⁶ result from secondary stimulation of the chief cells by the secreted hydrochloric acid.

A variety of other chemical substances, e. g. peptones, various meat extracts and liver extract stimulate gastric secretion when applied to the gastric or intestinal mucosa or in the case of some of them, when administered parenterally. Their mode of action has recently been discussed by Babkin.¹⁰

Of particular interest is an extract of the pyloric mucosa prepared by Komarov¹⁷ which acts very much like histamine on gastric secretion but possesses none of the other properties of histamine. It is, possibly, a substance concerned with the humoral stimulation of

gastric secretion. The fact that it, like histamine, acts mainly on the parietal cells suggests that hormonal stimulation of gastric secretion may be concerned primarily with the secretion of hydrochloric acid.

NERVOUS INHIBITORY INFLUENCES

The well known inhibitory effect on gastrointestinal motility of noxious stimuli is probably paralleled by inhibition of various secretions, although surprisingly little reference to such inhibition is to be found in the literature. Dogs that become nauseated and vomit during an experiment on gastric secretion cease to secrete acid for the time being and secrete instead large amounts of mucus. In acute experiments gastric secretion is inhibited for a time following the operative procedures, and stimulation of the secretory nerves is without effect.¹⁸

ACID AS AN INHIBITORY AGENT

Pavlov¹⁹ reported that the presence of an excess of hydrochloric acid in the stomach inhibits secretion of acid by the gastric glands. This observation was confirmed by McLean and Griffiths²⁰ and later by Wilhelmj, O'Brien and Hill.²¹ The former authors noted that the peptic activity of the juice increased during acid inhibition. Acid in the intestine also generally inhibits gastric secretion²² but negative results have been reported.²³ Whether or not inhibition occurs depends somewhat on the character and strength of opposing excitatory stimuli.²⁴ When the stimulus is alcohol the inhibitory effect of acid in the duodenum appears to influence mainly the parietal cells, since the peptic activity has been observed to increase during the period of inhibition. On the other hand, studies in progress in the Jefferson Physiological Laboratory suggest that, during the first half hour after feeding meat, acid in the intestine has little effect on the volume or acidity of the secretion from a Pavlov pouch but diminishes the output of pepsin.²⁵

THE EFFECT OF FAT

The most important inhibitor of gastric secretion is fat. The inhibitory effect is usually followed by secondary augmentation of secretion.²⁶ Although the

sideration After other exclusions made necessary by the roentgenologic approach, there remained 61 ulcerating carcinomas and 71 ulcers, of which 63 were benign and 8 (11.3 per cent) malignant. These figures are compatible, though not identical, with the generally accepted estimate that from 10 to 12 per cent of all gastric ulcers, including many that appear roentgenologically and macroscopically to be benign, prove to be malignant. This study thus supports the newer view that prepyloric ulcers are not more often carcinomatous than gastric ulcers in other situations.

On reflection it seems evident that the highly diverse estimates as to the incidence of malignancy in prepyloric ulcers result from varying definitions and applications of the term ulcer.

Of much greater importance than the exact incidence of malignancy in prepyloric ulcers as strictly defined is the fact that a large majority of the lesions in this part of the stomach are ulcerous and malignant.

THE MODERN CONCEPTION OF GASTRIC SECRETION

J EARL THOMAS, M.D.

PHILADELPHIA

Since the year 1870, when Heidenhain¹ discovered the chief cells (hauptzellen) and distinguished them from the parietal cells (belegzellen) of the gastric glands, the gastric juice has properly been regarded as a mixture of secretions produced by the various cellular elements of the gastric mucosa. Bensen² differentiated the chief cells of the neck from those of the body of the gastric glands. Lim³ confirmed Bensen's observations and suggested the name "mucoid cells" for the neck chief cells. In addition to the true gastric glands which are found in the body and fundus of the stomach and are made up of the elements already mentioned, the pyloric glands and the mucous cells of the surface epithelium contribute to the secretion.

The parietal cells are believed to secrete a relatively pure solution of hydrochloric acid of constant strength. Estimates by various authors of the secreted concentration⁴ range between 0.154⁵ and 0.2⁶ normal. The majority of the chief cells, exclusive of the neck cells, secrete pepsin,⁷ possibly with a certain amount of water

or neutral chloride solution. The "neck chief cells" (Bensen cells) are believed to secrete mucus⁸ which, however, differs from the mucus ordinarily seen floating in gastric juice in that it is either soluble or so suspended that its presence cannot be detected by inspection. It is, therefore, sometimes referred to as "dissolved mucus" (Webster and Komarov, cited by Baken⁹).

The cells of the pyloric glands have the same staining reactions as the neck chief cells² and on that account are supposed to form a similar secretion. Whether or not this secretion contains pepsin has been a subject of some controversy,¹⁰ but the preponderance of evidence, especially the recent work of Jennings and Florey,¹¹ indicates that the pyloric secretion contains a small amount of a proteolytic enzyme, presumably pepsin, which is active in acid solution. The visible mucus of the gastric juice is probably secreted by the surface epithelium.⁹

In addition to these specific secretions, the gastric juice contains nonprotein nitrogenous substances, including among other things amino acids¹²—amines (e.g., histamine), urea and ammonia. It also contains a variable quantity of neutral salts, chiefly chlorides. These substances may enter the gastric juice along with some of the specific secretions, or they may enter by simple diffusion from the blood. Some of them may be formed in the stomach by the interaction of various constituents of the secretion, for example, neutralization of hydrochloric acid or digestion of mucin.

The present discussion deals with the manner in which the various secretory elements of the gastric mucosa are activated and their secretion is regulated. The secreting cells are influenced by stimuli which either increase (excite) or decrease (inhibit) their functional activity. Some of these stimuli reach the glands by way of the nervous system, others which are of a chemical nature are carried by the blood stream or, possibly, formed in situ.

NERVOUS EXCITATION

Secretory fibers for the gastric glands are found in the vagus¹³ and splanchnic¹⁴ nerves. Vineberg¹⁵ observed that weak stimulation of the vagi caused a secretion consisting only of mucus and a small amount of pepsin. Stronger stimulation first increased the pepsin content of the juice and finally brought about a secretion of acid as well. In the light of the current conception of the "all or none" response of nerve fibers, these results indicate that the most irritable (to electric

obviously was in doubt as to the character and sometimes as to the exact site of the lesion, it is noteworthy that 5 of the ulcerating carcinomas were reported as being probably malignant.

A diagnosis of obstructing lesion at the pylorus was returned one hundred times. Benign prepyloric ulcer was found in only 9 instances, ulcerating carcinoma in 43, duodenal ulcer in 44, carcinoma of the pancreas in 3 and carcinoma of the gallbladder in 1. In 19 of the 43 ulcerating carcinomas the examiner suggested in his report that the lesion probably was malignant. When the pyloric canal is much obstructed, it is often difficult or impossible to determine whether the obstructing lesion is immediately at, above or below the pyloric ring, and when the lesion is a duodenal ulcer its depiction often is so unsatisfactory that the ulcer cannot be identified. This accounts for the high proportion of duodenal ulcers in this group.

In 17 cases a diagnosis of duodenal ulcer was made. In 2 instances the diagnosis was correct, but in both an accompanying prepyloric benign ulcer was overlooked. In the remaining 15 instances the lesion proved to be benign prepyloric ulcer in 9, malignant prepyloric ulcer in 1 and ulcerating carcinoma in 5.

PATHOLOGIC DATA

After the duodenal ulcers and the carcinomas of the gallbladder or pancreas were deducted there remained 132 prepyloric ulcerating lesions, of which 61 were frank tumefactive carcinomas with ulceration and 71 were ulcers. Of the 71 ulcers, 63 were benign and 8 (11.3 per cent) were malignant. This percentage would indicate that prepyloric ulcers are not more likely to be carcinomatous than ulcers situated elsewhere in the stomach, for it is accepted generally that from 10 to 12 per cent of all gastric ulcers, including many that appear grossly and roentgenologically to be benign, prove microscopically to be malignant. Thus the figures derived from this study are in consonance, though not identical with those of Singleton and are definitely at variance with those of Orator, Hampton and others.

COMMENT

Probable or potential reasons for these conflicting statistics and conclusions make an interesting theme for speculation. Differing bases and methods of calculation might account for some inconsistencies and disagreements but not for utterly contradictory data and deductions. It seems most likely, therefore, that the discordance arises from differing definitions and connotations of terms. Although not universally accepted or at least not always strictly applied, classification of the lesions under consideration as ulcers, malignant ulcers and ulcerating carcinomas is of practical value and is warranted by differences in their morphologic characteristics.

According to this classification, which we have employed in this study, the term "ulcer," with or without the qualifying adjective "benign" or "simple," implies a nonmalignant peptic ulcer, the crater of which is sculptured in the gastric wall, seldom has a diameter exceeding 2.5 cm and does not have any tumefaction of its borders except in the rather uncommon instances of callous ulcer. Roentgenologically the crater is exhibited as a true niche projecting beyond the normal confines of the gastric lumen, and adjacent rugae are likely

to be accentuated and convergent. The designation "malignant ulcer" is restricted conveniently and properly to a lesion that has the morphologic characteristics of benign ulcer but on microscopic examination is found to be carcinomatous. Its malignant character sometimes can be surmised if the crater is unusually large or has an irregular profile, or if tenderness to pressure or spastic manifestations are lacking. The term "ulcerating carcinoma" speaks for itself, but it is helpful to confine it to ulcerating carcinomatous tumors in which both ulceration and tumefaction are demonstrable, either macroscopically or roentgenologically, thus distinguishing these malignant tumors from malignant ulcers. In the small carcinomas with which this study deals ulceration is a conspicuous, even dominant, element, but commonly the crater thus produced has not penetrated into the gastric wall and is entirely within the tumor, the remnant of which persists as an elevated ring around the crater. Roentgenologically the tumefied ring usually is demonstrable under pressure as a transradiant halo about the ulceration, the crater appears as a pseudoniche that does not project beyond the normal limit of the gastric lumen, the lesion is not tender to pressure, rugae adjoining it are subdued or effaced and the meniscus complex thus exhibited is pathognomonic.

If the foregoing distinctions were applied uniformly in all studies of the incidence of malignancy in gastric ulcers the results should not be widely different. There can be little doubt that the conflicting data and opinions now current are due to differing conceptions of benign ulcers, malignant ulcers and ulcerating carcinomas. This is all the more probable because most of the small ulcerating carcinomas are conspicuously ulcerous, the ulceration commonly being more striking than the tumefaction, and it is not altogether illogical to regard them as malignant ulcers. If all prepyloric ulcerous lesions, regardless of size, degree of penetration and the presence or absence of visible tumefaction, are to be considered ulcers, then an overwhelming majority of them are indisputably malignant.

The latter consideration again brings up a point even more important than the precise incidence of malignancy in prepyloric lesions that properly or preterably may be called ulcers, and that point is the fact that among all prepyloric lesions, regardless of their morphologic variety, 4 out of 5 are malignant. The roentgenologist should be able to identify most cases of hypertrophy of the pyloric muscle and hypertrophic rugae, about half the benign ulcers and a greater proportion of ulcerating carcinomas large and small. But there will remain many small prepyloric lesions, as well as a few ulcers in the base of the duodenum, that he cannot diagnose specifically, and since a majority will prove to be carcinomatous, his report should be made in terms that will put the clinician on guard.

SUMMARY

The prevalent assumption that prepyloric ulcers are more likely to be malignant than ulcers situated elsewhere in the stomach has been challenged in recent years. To elicit information that may help to solve the question, ulcerous prepyloric lesions observed roentgenologically and operated on at the Mayo Clinic during the period 1937 to 1941 inclusive were reviewed, subject to commonly accepted conceptions and definitions of the terms "simple ulcer," "malignant ulcer" and "ulcerating carcinoma." All ulcerating carcinomas that had been diagnosed roentgenologically were excluded from con-

sideration After other exclusions made necessary by the roentgenologic approach, there remained 61 ulcerating carcinomas and 71 ulcers, of which 63 were benign and 8 (113 per cent) malignant These figures are compatible, though not identical, with the generally accepted estimate that from 10 to 12 per cent of all gastric ulcers, including many that appear roentgenologically and macroscopically to be benign, prove to be malignant This study thus supports the newer view that prepyloric ulcers are not more often carcinomatous than gastric ulcers in other situations

On reflection it seems evident that the highly diverse estimates as to the incidence of malignancy in prepyloric ulcers result from varying definitions and applications of the term ulcer

Of much greater importance than the exact incidence of malignancy in prepyloric ulcers as strictly defined is the fact that a large majority of the lesions in this part of the stomach are ulcerous and malignant

THE MODERN CONCEPTION OF GASTRIC SECRETION

stimulation) vagus fibers innervate only the surface epithelial cells, fibers of intermediate irritability excite the zymogenic chief cells or peptic cells or possibly only the mucoid or neck chief cells, which may also secrete some pepsin, and the least irritable fibers excite the parietal cells. Such a precise distinction between separate nerve fibers may apply only under special experimental conditions, but the more general conclusion that each individual type of gland cells is innervated by a distinct group of nerve fibers¹ appears to be justified. It may be further presumed that normal or pathologic reflexes may act selectively through one or another group of nerve fibers and thus influence the secretion of mucus, pepsin or hydrochloric acid separately.

Baxter¹⁴ found that stimulation of the splanchnic nerves induced secretion of mucus with slight peptic activity, chiefly from the pyloric portion of the stomach. He expressed the opinion that the secretion came from the pyloric glands rather than from the surface epithelium. The work of Vollborth and Kudryavtsev¹⁵ indicates that the splanchnics send a few fibers also to the parietal and chief cells of the gastric glands.

CHEMICAL EXCITATORY STIMULI

The best known chemical stimulus for gastric secretion is histamine. The secretion resulting from histamine stimulation contains a relatively large proportion of hydrochloric acid and a relatively small amount of pepsin and mucus¹⁶. Histamine, therefore, acts as a powerful stimulus for the parietal cells. Since "histamine juice" regularly exhibits some peptic activity,¹ however slight, histamine may also stimulate, but less powerfully, other secretory elements of the gastric glands. This is not a necessary conclusion since the pepsin present undoubtedly results, in some cases from contamination of the stimulated secretion with resting secretion, especially in human beings, or it may be washed out of the gastric glands by the free flow of hydrochloric acid,¹⁸ or it may, as suggested by Lim and Ma,¹⁷ result from secondary stimulation of the chief cells by the secreted hydrochloric acid.

A variety of other chemical substances, e.g. peptones, various meat extracts and liver extract, stimulate gastric secretion when applied to the gastric or intestinal mucosa or, in the case of some of them, when administered parenterally. Their mode of action has recently been discussed by Babkin.¹⁹

Of particular interest is an extract of the pyloric mucosa prepared by Komarov²⁰ which acts very much like histamine on gastric secretion but possesses none of the other properties of histamine. It is, possibly, a hormone concerned with the humoral stimulation of

gastric secretion. The fact that it, like histamine, acts mainly on the parietal cells suggests that hormonal stimulation of gastric secretion may be concerned primarily with the secretion of hydrochloric acid.

NERVOUS INHIBITORY INFLUENCES

The well known inhibitory effect on gastrointestinal motility of noxious stimuli is probably paralleled by inhibition of various secretions, although surprisingly little reference to such inhibition is to be found in the literature. Dogs that become nauseated and vomit during an experiment on gastric secretion cease to secrete acid for the time being and secrete instead large amounts of mucus. In acute experiments gastric secretion is inhibited for a time following the operative procedures, and stimulation of the secretory nerves is without effect.²¹

ACID AS AN INHIBITORY AGENT

Pavlov²¹ reported that the presence of an excess of hydrochloric acid in the stomach inhibits secretion of acid by the gastric glands. This observation was confirmed by McLean and Griffiths²² and later by Wilhelmj, O'Brien and Hill.²³ The former authors noted that the peptic activity of the juice increased during acid inhibition. Acid in the intestine also generally inhibits gastric secretion,²⁴ but negative results have been reported.²⁵ Whether or not inhibition occurs depends somewhat on the character and strength of opposing excitatory stimuli.²⁶ When the stimulus is alcohol, the inhibitory effect of acid in the duodenum appears to influence mainly the parietal cells, since the peptic activity has been observed to increase during the period of inhibition. On the other hand, studies in progress in the Jefferson Physiological Laboratory suggest that, during the first half hour after feeding meat, acid in the intestine has little effect on the volume or acidity of the secretion from a Pavlov pouch but diminishes the output of pepsin.²⁷

THE EFFECT OF FAT

The most important inhibitor of gastric secretion is fat. The inhibitory effect is usually followed by secondary augmentation of secretion.²⁸ Although the

initial effect of fat is to depress all secretory elements of the gastric glands, secretion can be stimulated by appropriate means an hour or so after the fat has been given. Secretion obtained under these circumstances may be of approximately normal volume and acidity but possesses very little peptic activity.³¹ Evidently fat inhibits the pepsin secreting elements of the gastric glands more powerfully at this stage than those responsible for secretion of water and hydrochloric acid. The selective inhibitory effect of fat on the pepsin secreting cells is particularly well shown following the administration of pilocarpine. In experiments reported by Alley and Babkin,³² although fat failed to affect the volume of the secretion elicited by pilocarpine the peptic power was reduced about two thirds. The secondary augmentation of secretion by fat also apparently affects the zymogenic cells first, since the peptic power of the gastric juice in human beings has been observed to increase²⁹ following fat inhibition before there was any recorded increase in volume or acidity.

THE EFFECT OF DEXTROSE

Dextrose in the intestine generally inhibits gastric secretion³³ but when given orally one-half hour before alcohol is administered it has been observed³⁴ to increase the total output of pepsin while diminishing the volume of the secretion. The effects of dextrose when given intravenously³⁵ are complex and appear to depend on the amount and concentration of the dextrose solution injected and the nature of the stimulus used to provoke secretion. The secretion produced by insulin (hypoglycemia) is readily inhibited by intravenous dextrose. On the other hand, severe grades of hypoglycemia, even though insufficient to cause symptoms, may inhibit gastric secretion.³⁶

CHEMICAL INHIBITORS OF GASTRIC SECRETION

Since fat in the intestine inhibits secretion in gastric pouches without a nerve supply³⁷ a humoral mechanism is necessarily involved. This does not exclude the possibility, suggested by the predominant effect of fat on enzyme secretion, that the inhibition in the intact animal is primarily reflex, but the proved existence of an inhibitory humoral mechanism is important theoretically and also because of its clinical possibilities. An extract of intestinal mucosa which had been in contact with fat was prepared by Kosaka and Lim³⁸ and was shown to inhibit the gastric secretory response to a meat meal in Heidenham pouch dogs. They proposed the name "enterogastrone" for the active agent. This substance has since been studied extensively by Ivy and his co-workers, who have succeeded in preparing it in relatively pure form.³⁹

More recently a substance has been extracted from the urine of normal men and women and also from the urine of experimental animals which has an action similar to that of enterogastrone.³⁹ The inhibitory substance in urine has been designated "urogastrone."⁴¹ This or another substance closely associated with it has been used with good results for the prevention (in dogs) or treatment (in patients) of peptic ulcer.⁴²

Unfortunately no information is available regarding possible selective inhibition of specific secretory elements of the gastric glands by enterogastrone or urogastrone, but since depression of acid secretion has been used in the study of these substances as the criterion of inhibition it may be assumed that the parietal cells at least are involved. The known selective action of fat suggests a study of the possible inhibitory effect of these agents on the peptic cells.

INTERNAL SECRETIONS AND VITAMINS

Since the publication of Keeton's⁴³ work in 1914 it has been known that parathyroidectomy adversely affects gastric secretion. Keeton found that in cats removal of the parathyroids and the subsequent decrease in blood calcium resulted in a decrease in volume, acidity and especially peptic activity of the gastric juice. The condition was improved by administration of calcium. More recent studies have shown that increase in blood calcium following administration of activated ergosterol⁴⁴ or solution of parathyroid⁴⁵ has a like effect, especially on the reflex or nervous phase of secretion,⁴⁴ it has little or no effect on the response to histamine.⁴⁶ Recently, Gray and Adkison⁴⁷ have studied acid secretion by the isolated gastric mucosa of the frog's stomach. They found that either an increase or a decrease in the calcium concentration above or below 2.5 milliequivalents per liter in the solution in which the mucosa was immersed decreased its capacity to secrete acid. Apparently the normal blood calcium is optimal for the gastric glands, as it is for other bodily functions.

Thyroidectomy⁴⁸ and thyroparathyroidectomy⁴⁵ have been reported to increase the volume of the gastric secretion. Following the latter operation the peptic activity and total pepsin secreted were reduced in spite of the increase in volume, the blood calcium was reduced to about 7 mg per hundred cubic centimeters. Correcting the calcium deficiency restored the volume of the secretion but not the peptic activity to normal.

Various vitamin deficiencies, particularly of the B complex, may affect gastric secretion.⁴⁹ Absence of the B complex from the diet of dogs results in achlorhydria,⁵⁰ which is readily cured by administration of yeast. Which of the B vitamins is responsible for the effect has not been determined. B₁ deficiency did not affect gastric secretion in rats.⁵¹ The vitamins probably owe their influence on gastric secretion to their effects on the nutritional state of the secreting cells and are not to be regarded as gastric secretory stimulants in the sense in which the term is being employed here. A possible exception is nicotinic acid, which is said to have a histamine-like effect on gastric secretion.⁵² The literature has recently been reviewed by Wilbur.⁵³

COMMENT

While surveying the action of the various stimuli which either increase or decrease gastric secretion, one is impressed with the frequency with which individual stimuli have been found to affect more or less exclusively the secretion of some one component of the gastric juice, such as mucus, pepsin or hydrochloric acid. It has been assumed,⁵⁴ but without any considerable body of systematic evidence to support the assumption that such stimuli as are capable of provoking gastric secretion stimulate simultaneously all the various types of gland cells which may contribute to the secretion. Obvious variations in composition of the gastric juice were referred to differences in the rate of secretion, certain cells being supposed to respond more vigorously than others to increasing intensity of stimulation.

The point of view which I choose to call "the modern conception of gastric secretion" is the exact opposite of that just outlined. It is the result largely of researches carried out at McGill University in Montreal by Prof. B. P. Babkin and his pupils and the interpretation of these researches by Dr. Babkin.⁵⁵ Babkin finds that "The secretory activity [of mixed glands] is not regulated *en masse* but various nerves or chemical agents stimulate or inhibit each set of secretory elements separately."

If this conception is correct and the evidence seems to me to indicate that it is, one may consider the possibility of regulating for therapeutic purposes not only the volume but the composition of the gastric secretion. Such an attainment would doubtless require as a preliminary a considerable increase in our knowledge, but there appear to be no insurmountable obstacles in the way of acquiring the necessary information.

PSYCHOSOMATIC CORRELATIONS OF
DUODENAL ULCER

A STATISTICAL STUDY

SAMUEL MORRISON, M.D.

AND

MAURICE FELDMAN, M.D.

BALTIMORE

For many years we have been impressed by the fact that cases of duodenal ulcer present a characteristic constitutional psychosomatic pattern. The psychosomatic aspect of disease, with especial reference to its association with duodenal ulceration, has been considered by many authorities as an important contributory factor in the production and intensity of symptoms in peptic ulcer. Psychosomatic phenomena have been strongly emphasized in recent years, although their importance as etiologic factors have not been truly evaluated.

We have undertaken the study of a series of 208 consecutive cases of duodenal ulcer in an effort to correlate any relationship with psychosomatic changes. In this study we have especially noted the general psychoneurologic manifestations and their relation to the activity of the ulcer. We have restricted ourselves to overt manifestations (behavior, emotional attitudes, personality changes) in helping to form our psychosomatic impressions. We have also tried to evaluate the physiologic changes which are responsible for the digestive symptoms and have correlated both these phases with respect to their relationship with duodenal ulceration. The psychoneurologic symptoms most frequently noted were the general demeanor of the patient, the hyperirritable sensitive type, and his somatic response to nervous tension, i. e. tenseness, anxiety, irritability, restlessness, sensitivity and various types of emotional instability and vasomotor disturbances such as sweating and flushing.

These patients are usually not well adjusted, partly because they are constantly annoyed by more or less stomach consciousness. Often they are unable to rest well or sleep well at night, being awakened by gnawing discomforts. Lack of rest is partly responsible for their inability to meet situations, their loss of confidence in themselves and their failure to contribute what they would consider a satisfactory day's work. Many of them are discouraged because they were supposed to have been cured of their ulcer one or more times. In the latter instance the physician may be open to criticism in failing to inform the patient that his program of eating, rest and activity will be restricted to a greater or less degree for an indefinite period. Partly because these patients are restricted in their range of activity they often become introverted and do not mix well with others. Restrictions of diet, for example, may cause them embarrassment and sensitiveness when they cannot partake of stimulants and foods such as others and in the presence of others. Nevertheless, many of these patients are very keen and very alert (a part of their general condition of being high strung) and sometimes one gets the impression that they overcompensate for their restricted life by doing certain

Read in the Panel Discussion on Ulcer before the Section on Gastroenterology and Proctology at the Ninety Third Annual Session of the American Medical Association, Atlantic City, N. J. June 11, 1947.

things exceedingly well. This state of the nervous system undoubtedly contributes to the patient's symptoms and often determines how severe, symptomatically speaking, an ulcer will be. Very often the nervous symptoms overshadow the actual organic disease. Interestingly enough, these patients are often of the type who live and work under tension, many of them are of the so-called executive type. One rarely encounters a phlegmatic patient with a duodenal ulcer, although ulcers do occur in such individuals. It is noteworthy that there is a correlation between the nervous spastic phenomena observed in the roentgenogram and the personality changes. Of the 208 patients, the nervous phenomena were particularly striking in 150.

Since no adequate explanation of the etiology of ulcer has yet appeared there is no harm in suggesting that a train of events such as this may occur. Repeated duodenal irritability leads to ischemia and loss of local viability, which when acted on by irritating boluses and acid finally culminates in necrosis of tissue and consequent ulcer. It would appear, therefore, that the play of impulses, the autonomic and central nervous system, the endocrines and what we here stress as a psychosomatic pattern is more intimately bound up with the production of duodenal ulcer than we now are able to explain. In the present state of our knowledge it must be admitted that such a relationship is often difficult to prove.

The intermittence of ulcer symptoms and their activation are not adequately explained even today. The question arises as to whether the periodic changes in personality tension contribute to the periodicity of ulcer. Furthermore, the relationship of the whole ulcer syndrome to the autonomic nervous system remains a mystery. The activation of nerve impulses by chemical means has now come to the fore, the relationships of the endocrine to various diseases and the hormonal and enzymatic aspects of disease are all intimately related to the central nervous system, and it is these factors which determine the constitutional type. It is our definite belief that the ulcer psychosomatic pattern is so distinct as to lead one frequently to suspect the condition even before a complete examination is made.

Early in adolescence in certain individuals a psychosomatic pattern is developed which is frequently characterized by three basic phenomena, namely hypersensitivity, hyperirritability and hyperactivity of the body tissues. It is our opinion (and we hope it is possible to follow up with more detailed studies) that tests of bodily functions would indicate a positive rather than a negative balance, by which we mean that the organism is hyperactive instead of hypoactive. If careful histories are taken it will be found that a large number of cases of digestive complaints frequently due to early ulceration begin during adolescence. With the newer knowledge of hormones and humoral elements (such as the action of urogastrin) involved during the adolescent period, it would appear that a change in the normal physiologic mechanism of body function may play a predominant role in determining the ulcer pattern.

It is highly important to take the patient's history very carefully, since otherwise it will signify only the present and immediate continuous state of the digestive complaints. The patient will not voluntarily give a history dating back to the onset unless an effort is made

to obtain this information. Therefore, many histories will not give a true picture of the actual age of onset. Patients with complications such as hemorrhage or obstruction may give a history of only very recently having any digestive trouble, and sometimes there appears to be no complaint until actual hemorrhage or other complications occur. This point is stressed because we are of the opinion that the age of onset can frequently be correlated with physiologic changes that occur during adolescence. We further believe that the psychosomatic pattern begins to form at this time.

We have endeavored to correlate the clinical manifestations of duodenal ulcer with gastric analyses and gastrointestinal roentgenographic studies. In the series of 208 proved cases of duodenal ulcer it was found that 166 were clinically active. It is interesting to note that most of these cases presented x-ray evidence of spastic and irritable phenomena throughout the entire gastrointestinal tract. Moreover, 61 of our series of 208 cases showed x-ray evidence of an ulcer niche, which is a demonstration of the objective anatomic change indicating activity of the ulcer, although the absence of a niche does not exclude activity.

Furthermore, one can readily observe the effect of the somatic changes on the bowel because most of the duodenal ulcer patients present certain bowel symptoms such as changes in type and frequency of stools, mucous colitis and irritable and spastic colon which were associated with the duodenal ulcer. The correlation of the stool habits with the roentgenologic and clinical manifestations of the duodenal ulcer picture lead to a fairly consistent history. The patients are usually on the constipated side often owing to spastic changes. Many of them are liquid petrolatum addicts, and though they may have occasional loose, frequent or soft stools, which they may describe as temporary diarrhea, this is not very common. The usual description of the stool is as follows: a flattened, ribbon or small segmented stool the bulk of which is also small. Very often many bowel movements may be had during the day, but added together they would really amount to only one satisfactory stool. These stools also often contain dried mucus and not uncommonly mucous casings and mucous strings. In 3 cases the roentgen examination revealed the string sign of mucous colitis. There are occasional cases in which the mucus is passed in large amounts, so much so that the bowel picture becomes predominant temporarily over the ulcer syndrome.

Interestingly enough, the ulcer symptoms are often brought under control by appropriate therapy, but the bowel symptoms remain the predominant feature in many cases. Clinically, we have noted in this series of 208 cases that 109 presented evidence of periodic cramps related to the bowels. It is noteworthy too that on examination of the stools the gross appearance in 53 cases presented evidence of spasticity. It was of interest to correlate these clinical neurologic bowel signs with the roentgenologic manifestations. Thus, of the 208 cases, 80 presented roentgenographic signs of an irritable spastic colon. The appearance or presence of spastic states of the colon is not only a local bowel condition but apparently a manifestation of a constitutional reaction. For example, in addition to the spastic phenomena noted in the bowel, 81 of these cases presented evidence of a spastic pylorus. From our statistics it would definitely appear that psychosomatic and neurologic findings are a part of the general picture.

of duodenal ulcer, i. e. a general irritability in the personality as a whole and in various localities in the digestive tract in which the irritability expresses itself in spastic changes

There is such a thing as prophylaxis of ulcer because a preulcer constitutional state can actually be determined. For example, it can be foretold that those individuals who present the characteristic psychosomatic ulcer pattern, especially when such a pattern is associated with spastic and irritable states of the gastrointestinal tract and hyperacidity, will likely fall into the ulcer group, by which we mean that their chances for developing anatomic ulcer changes are much greater than the average group. Though this analysis brings us no nearer to the explanation of the formation of an ulcer, it does give us a basis for prophylaxis and a preulcer treatment which thus far has been sadly neglected. We likewise believe that when more attention is directed to the psychologic aspects of ulcer, with their psychosomatic components, the proper therapy will lead to a far greater percentage of cures or arrested cases than does our present approach to the problem, especially if such attention is instituted in the early stages. As a prophylactic measure, therefore we have made it a rule to devote a good part of our therapy to an educational and rehabilitation program regarding the condition and to a modified personality study with the object in view to remove as far as is possible the tense, anxious background reflected in the various psychosomatic changes.

Such questions as the frequency of duodenal ulcer in males rather than females and in younger rather than older patients also suggest the possibility of an endocrinologic and nervous system background. The fact that this pattern is so frequently and consistently seen in adolescent males, even before the development of ulcer symptoms, is a point to be considered as significant in the prophylaxis. Often patients, when carefully interrogated, relate the onset of digestive symptoms to a time which shows that the condition actually began in adolescence. It apparently takes a certain but varying period of time before the persistent ulcer symptoms fully develop. Therefore, there seems to be a long period of latency during which prophylactic therapeutic measures could be instituted. We believe that the type of individual with the constitutional pattern described has periods in which spastic irritable states of the digestive tract are present without demonstrable ulcer which only later develops into a characteristic ulcer picture in a certain proportion of cases. Many apparently overcome these preliminary psychosomatic states before actual organic disease develops. Some are constitutionally unable to adjust themselves, and as a consequence the combination of their psychosomatic pattern with the various physiologic changes often leads to the development of an ulcer.

SUMMARY

A study of 208 cases of duodenal ulcer was made to correlate the psychosomatic changes with the activity of the ulcer. A distinctive pattern was observed which was localized not only in the duodenum but also in the digestive tract and in the constitutional behavior of the patient. This pattern proved to be characterized by hypersensitivity, hyperirritability and hyperactivity which involved the affected duodenum, the digestive tract as a whole and the personality. Statistics relating

to the incidence of the various psychosomatic phenomena associated with duodenal ulcer reveal a frequency which leads to a definite psychosomatic-ulcer pattern. In the cases studied there appeared to be a remarkable similarity of psychosomatic features which were conspicuous enough to lead to a correlation with the existing duodenal ulcer. It also appeared that psychosomatic influences may possibly represent an etiologic factor in the production of duodenal ulcer, although the mechanism requires further elucidation. This study suggests a prophylactic approach to the problem of duodenal ulcer, since a general constitutional pattern is disclosed which often antedates the actual appearance of the ulcer.

THE PHYSIOLOGIC BASIS FOR THE DIETOTHERAPY IN DUODENAL ULCER

HARRY SHAY, MD

JACOB GERSHON COHEN, MD, DSc (Med)

SAMUEL S. FELS, LL.D.

AND

HERMAN SIPLIT, AB

1114 DELI III V

Diet in cases of duodenal ulcer is based on certain well established principles—that the foods are non-irritating, are not stimulating to gastric secretion and have a good acid combining power. Milk and cream have met these demands so well that they have come to play the basic part in ulcer diets. Khigine¹ many years ago, in comparing the response of dogs with a Pavlov pouch to meat, bread and milk, found that milk called forth a secretion lowest in volume and peptic activity. The acid combining power of milk and cream has also been adequately stressed. These foods, however, have in addition an action on the disordered gastric function responsible for much of the ulcer symptomatology. This action is perhaps less often considered yet in the final analysis is probably responsible for the most important influence of these food stuffs in duodenal ulcer. It is the latter activity that we wish especially to emphasize, since we now have such a clear understanding of the mechanism involved.

Uncomplicated duodenal ulcer is characterized by certain changes in gastric function—hypermotility, hyperperistalsis, hypertonicity and hypersecretion. We believe that these abnormal gastric conditions are caused by alterations in duodenal function brought about by the ulceration and its associated duodenitis. In the normal person the duodenum houses a mechanism or mechanisms, which normally is stimulated by the gastric hydrochloric acid or by some ingested foods brought to the duodenum which help to control both gastric motor and secretory function. In duodenal ulcer this duodenal function is depressed, fails to respond

to the normal stimuli and results in the abnormal gastric phenomena seen in this disease

That milk has a high acid combining power has been demonstrated by Freezer, Gibson and Matthews.³ They found it capable of combining with its own volume of 0.3 per cent hydrochloric acid. While this represents a decided buffering effect, it probably represents the lesser effect of the milk, and especially of cream, in allaying symptoms of duodenal ulcer. We believe that the major beneficial action of milk and cream occurs only after these substances leave the stomach.

If a normal person is given a water-barium meal by mouth, the gastric evacuation time will be greatly prolonged if milk is substituted for the water and still further prolonged if the barium meal is prepared with cream (fig 1 rows 1, 2 and 3). In analyzing the nature of this action we⁴ found that the mechanism responsible for delayed gastric evacuation was in the upper small intestine (fig 1, rows 4 and 5) and was activated by chemical⁵ or physical⁶ agents reaching the duodenum. Of these, fat was found to be very effective and the greater efficiency of cream over milk would thus doubtlessly be due to the higher fat content of the former. We have previously shown⁵ that stimulation of this duodenal mechanism not only delays gastric evacuation but also reduces gastric peristalsis and tonus. The stomachs of patients with duodenal ulcer respond in quite similar manner to milk and cream meals as well as to their instillation into the duodenum while a water-barium meal is administered by mouth.⁴ Thus these substances cut down intragastric acidity by combining with the hydrochloric acid in the stomach and in addition, on reaching the duodenum help to overcome the abnormal gastric motor phenomena—hypermotility, hyperperistalsis and hypertonicity. It becomes clear then why, from their effect on the gastric motor phenomena, milk and cream have kept their place on the ulcer diet.

Do milk and cream have other effects on gastric acidity besides gastric neutralization? Recently Everly and Breuhaus⁷ reinvestigated the acid neutralizing power of milk in vitro and found the action to be less when the fat content was higher. While perhaps true for their buffering action, nevertheless the gastric acid reducing power of milk in vivo is greater the higher its fat content. This, however, is due to the action of the milk and cream on reaching the duodenum. It has been demonstrated⁸ that man's duodenum houses a mechanism which, when stimulated chemically or physically, causes a depression in gastric secretion. This duodenal acid control mechanism may be activated

by the gastric hydrochloric acid itself as in the one concerned with gastric motor function, if it reaches the duodenum in proper concentration.² It may also be activated by hypertonic solutions of nonelectrolytes⁹ like dextrose, or by electrolytes⁹ like sodium chloride, and sodium bicarbonate. Too, it has been shown⁸ that fats are especially potent in causing this activation. It is the fat content of milk and cream which determines the intensity of the inhibiting power of these foods (fig 2). In many instances milk alone is not adequate to stimulate the gastric acid-reducing duodenal mechanism. Cream, however, in all cases caused a reduction of gastric acid when instilled slowly into the duodenum.

Figure 2 clearly illustrates the variations in gastric motility and acidity caused by different fat contents of milk and cream. To a patient a meal of 30 Gm of zwieback and 300 cc of water was administered and the usual fractional gastric analysis performed. Curve I was the result obtained for the free hydrochloric acid. A peak acidity of 81 clinical units was obtained and at one hundred and twenty minutes the stomach was

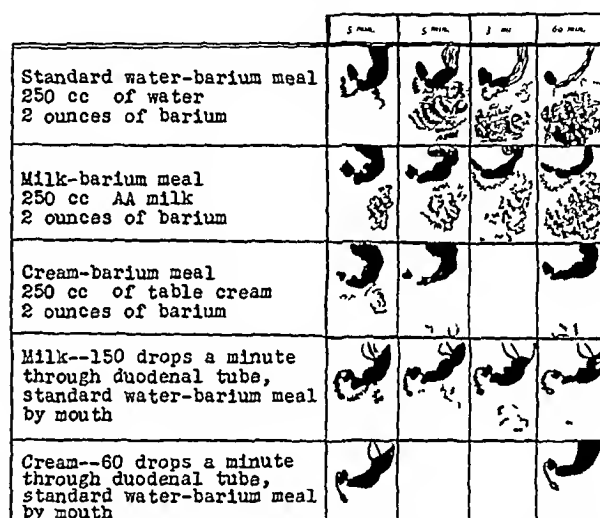

Fig 1—Pen and ink drawings made to scale from roentgenograms. The stomach empties completely a 250 cc water and barium meal in sixty minutes (row 1). When milk was substituted for the water a 30 per cent gastric residue was found at the end of a similar period (row 2). At another time the substitution of table cream for milk in the meal resulted in a 90 per cent stomach residue at the end of one hour (row 3). That the gastric motor delay caused by milk and cream is dependent on their reaching the duodenum was strikingly demonstrated by the effect on gastric emptying when these agents were instilled directly into the duodenum and a water and barium meal given by mouth (rows 4 and 5). Again the more striking effect is seen when cream is used. 100 per cent gastric residue at sixty minutes when only sixty drops of cream a minute was instilled into the duodenum (row 5) and a very slight gastric emptying when as much as 150 drops of milk a minute was instilled into the duodenum under similar experimental conditions (row 4).

completely empty. A similar test meal was given on another day and skim milk was simultaneously instilled into the duodenum at the rate of 50 to 60 drops a minute, curve II was the result of the fractional test. While there was no significant change in the peak of the free acidity, a striking delay in gastric evacuation did occur. Under these conditions the stomach showed a gastric residue of 18 cc at the end of one hundred and eighty minutes. Again, under similar test conditions, when a milk was substituted for skim milk, the gastric motor delay was still evident (curve III). Although the free acid curve is slightly lower, this change cannot

be considered significant. When on another day, however, cream was instilled into the duodenum under test conditions similar to those described, a much greater gastric motor delay was produced (190 cc gastric residue to one hundred and eighty minutes (curve V). An unmistakable depression of gastric acidity also took place.

The effect on gastric motility of milk and cream when they reach the duodenum, coupled with the depression of gastric secretion through the action of cream, make their time honored use in ulcer diets easily understandable. An appreciation of the mechanism of their action makes clear the reason they have retained their position in the ulcer diet at a time when fashions in treatment change so quickly for a disease whose cause is so poorly understood as that for peptic ulcer.

Olive oil too holds a traditional place in the treatment of hyperacidity. Its effectiveness in stimulating the gastric motor and secretory control mechanisms (fig. 3) on reaching the duodenum is even greater than that of cream.

The effect of the addition to the standard diet of small quantities of olive oil on the gastric secretion in dogs with a Pavlov pouch was recently demonstrated by the Komarovs.¹⁰ They found that a single small dose of olive oil introduced into the main stomach a short time before a test meal of meat reduced the volume, acidity and pepsin content of the gastric juice secreted by the pouch. This inhibition was especially noticeable during the first two or three hours post cibum. They also found that the daily addition to the standard diet of a similar small dose of olive oil inhibited gastric secretion more or less uniformly throughout the twenty-four hour period of observation. The rationale, therefore, of administering olive oil fifteen to thirty minutes before meals to patients with duodenal ulcer and hyperacidity who can tolerate the oil by mouth is

Fig. 2—Free acid curves (milk or cream instilled into the duodenum—Ewald meal by mouth)

based, therefore, on sound physiologic facts. Of further significance are the demonstrations on dogs by Day and Komarov¹¹ and by ourselves⁸ on human subjects that the duodenal mechanism concerned in the control of gastric acidity affects largely the nervous phase of secretion. Since the duodenal ulcer patient is so often

one with an autonomic nervous system imbalance of the parasympathetic-tonic type, we believe that these observations are especially pertinent.

SUMMARY AND CONCLUSIONS

Milk and cream have long enjoyed a unique position in the dietotherapy of duodenal ulcer. Through a high acid neutralizing power they exert a beneficial effect

Fig. 3—Free acid curves (olive oil instilled into the duodenum—Ewald meal by mouth)

in the stomach. After reaching the duodenum, and largely by the action of the fat content, they stimulate at least two mechanisms which bring about gastric motor and secretory inhibition. In this way they favorably influence the abnormal gastric motor phenomena seen in uncomplicated duodenal ulcer, namely hyperperistalsis, hypertonicity, hypermotility and hypersecretion.

It is clear that the threshold of response for the duodenal gastric motor mechanism is lower and requires a lesser stimulus than does the duodenal gastric secretory mechanism.

It is quite possible in the light of the conditions described that uncomplicated duodenal ulcers which fail to respond to an adequate course of medical therapy are, in some instances, ones in which the duodenal mechanisms described are so obtunded that they fail to react to the usual dietary agents which bring these mechanisms into play when they reach the duodenum.

Acting in the same capacity, but even more effectively and only on the duodenal mechanisms, is olive oil, an agent which holds a time honored place in the treatment of gastric hyperacidity.

Since medical opinion is again giving to gastric hyperacidity its proper value in the causation of peptic ulcer,¹ a disturbance of the duodenal mechanisms described may well explain at least one way in which ulcer is produced. Thus one may visualize a series of events as follows: a disturbance in the duodenal mechanisms described, in which their threshold of response is raised (e.g. duodenitis from one cause or another), resulting in (a) gastric motor changes producing hypermotility and increased evacuation with a consequent increased trauma to the duodenal cap and (b) gastric secretory changes which result in hypersecretion which add further trauma to the duodenal mucosa, conditions under which ulcerations may then occur.

INTRAGASTRIC DRIP THERAPY FOR
PEPTIC ULCER

A SUMMARY OF TEN YEARS' EXPERIENCE

ASHER WINKELSTEIN, M D

ALBERT CORNELL, M D

AND

FRANKLIN HOLLANDER, P H D

NEW YORK

In 1932 one of us¹ devised the intragastric drip therapy for peptic ulcer. This therapeutic procedure was based on two ideas. 1. Whatever the ultimate cause of peptic ulcer may be, free hydrochloric acid plus pepsin is a prime factor in the development and persistence of the lesion. 2. Methods which are most effective in the neutralization of the free acidity throughout the twenty-four hours of the day are most likely to be successful in the medical therapy of peptic ulcer. In view of the fact that all previous methods of controlling the interdigestive secretion have been found inefficient, particularly throughout the longest interdigestive period, viz., the night,² the drip therapy was devised as a logical and fairly simple method of attaining this goal. The efficacy of the drip method in neutralizing gastric acidity is discussed in detail elsewhere.³

Suffice it to say that our studies indicate that both milk-sodium bicarbonate and alumina gel preparations are effective in raising the gastric p_H on the average from 1.5 to 4.0. Since free acid does not exist above a p_H of 3.5 and since 90 per cent of peptic activity is eliminated at a p_H of 4.0,⁴ the digestive action of the hydrochloric acid-pepsin mixture is practically eliminated by this procedure, particularly during the night, when other forms of medication are usually discontinued.

The drip acts continuously and regularly, and its effectiveness may be due in part to the rationale of giving small doses of an antacid continuously rather than large doses intermittently. Frequent Sippy feedings may in themselves serve as a stimulus to increased acid secretion and may not allow sufficient functional rest, both motor and secretory. Furthermore, it does not seem logical to protect the ulcer crater for half of the day in order to allow granulation tissue to form and then to expose it to the strong corrosive action of gastric juice for the remainder of the twenty-four hours.

The original intragastric drip method devised by one of us (A. W.) was based on the excellent buffer properties of a mixture of milk with sodium bicarbonate and on the fact that milk provides good nutrition. It may be employed in the treatment of esophageal, gastroduodenal and gastrojejunal ulcer, but it is contraindicated in pyloric obstruction and in renal disease because the absorbable alkali may aggravate a systemic alkalosis, it is also contraindicated in patients who manifest aller-

gic reactions to milk or who experience intestinal disturbances from it. In such cases the milk-sodium bicarbonate may be replaced by a nonabsorbable alkali, this will be discussed later. Originally this drip was administered continuously throughout the twenty-four hours of the day for two to three weeks. In recent years the treatment has been modified as follows. The patient receives three liberal bland meals daily and atropine with the usual sedatives. One hour after each meal the drip is started, and it is continued until one hour before the next meal—even while the patient sleeps at night.

Since 1934 the use of nonabsorbable alkalis for antacid therapy has become increasingly popular. Of these various preparations, gels of aluminum hydroxide and phosphate have the further advantages of being astringent and antipeptic, and they lend themselves readily to use in a drip apparatus.⁵ Hence these two colloidal preparations can be substituted for the milk-sodium bicarbonate drip in conditions in which the latter is contraindicated and even offer certain advantages over the milk treatment. On the other hand, the lower cost of the milk, its nutritive value and the simplicity of the apparatus required for its administration all favor the use of the older form of drip medication whenever conditions permit.

DESCRIPTION OF DRIP
APPARATUS AND
TECHNIC

Because of the viscous nature of the alumina gels, it is necessary to employ an apparatus somewhat more complicated than the gravity drip flask that is employed for the milk drip. Our modification⁶ of a common type of such apparatus has been employed in this hospital since January 1940 with satisfactory results. In setting up the drip (illustrated) one first fills the reservoir⁶ with the preparation to be used. At present we employ aluminum phosphate gel diluted with 4 volumes of water, in preference to aluminum hydroxide, because it is less viscous and less constipating but no less effective as an intragastric neutralizer.

The rubber cap (B) is slipped over the neck (E) of the reservoir and both the upper clamp (F) on the air valve and the lower one (K) below the reservoir leading to the drip bulb are closed tightly. The lower clamp is then opened completely and kept that way while the drip is running. If the valve is airtight, a few cubic centimeters of fluid will run into the drip bulb (G), after which the flow will cease entirely. To start the flow of fluid the upper screw clamp (F) is next opened sufficiently to allow a free flow of material,

Sketch of apparatus for
intragastric drip

it is then closed gradually until the desired rate of flow (15 to 20 drops a minute) is obtained. At any time thereafter the flow can be stopped completely by closing the lower screw clamp (*K*), to start it again the latter need only be opened to its full extent. If difficulty is encountered in starting the flow of material, because of air trapped in the tubing (*H*) which connects the drip bulb (*G*) to the indwelling gastric tube, the air can be milked upward into the drip bulb in the usual way. An air vent (*J*) in the latter allows this air to escape. Should some of the gel settle out in the course of a treatment, it will be found that this does not interfere with the rate of flow to any considerable extent. On agitating the flask in order to redispense the gel, one must take care not to plug the lumen of the air inlet valve with the fluid.

Two types of indwelling thin gastric tubes are in use at this time. The more common form is the semirigid Levin tube (14 to 16 French), but because this may be irritating to the patient's throat over a long period we prefer the soft latex tube, originally employed by Woldman for nasogastric instillation. Most patients are hardly aware of its presence and prefer it to the stiffer Levin tube. Furthermore, the latex tube is less likely to become obstructed by the gel, mucus or food and it permits of an easier outflow of the drip material because of its open end. The tube is passed into the stomach through the mouth, the procedure being facilitated by dipping its end into liquid petrolatum and by having the patient drink some water while swallowing it. A silkworm gut stilet, extending to within 2 inches of the end of the tube, acts as a guide in passing it and prevents its complete occlusion. The stilet usually is allowed to remain in situ after the tube is swallowed. However, after the tube is removed from the patient the stilet must be taken out and allowed to dry under tension, by means of a hemostat or some other object attached to its lower end, in order to prevent its curling.

The tube need not extend deep into the stomach but may hang just below the cardia. It has been employed with good results even in the lower part of the esophagus for esophageal and high gastric ulcers. In this position, when the drip is used in cases in which there is a bleeding ulcer, one does not have to worry about possible dislodgment of the blood clot. One may estimate the length of tube to be inserted by measuring the distance in a straight line from the nuchal process up the midline of the chest neck and lower jaw to the lips. The tube may be fastened to the cheek by Scotch cellulose tape or ordinary adhesive. Dentures are removed before the tube is passed, and if the patient has an anterior or lateral tooth missing the tube can rest in the vacant space. It is important that the rubber tube, which connects the drip apparatus to the intragastric tube, is long enough so that the patient can turn in bed comfortably, especially during the night.

When milk is employed instead of an albuma gel a simpler apparatus may be used. This consists of a gravity flask or can attached to the intragastric tube through a rectal drip bulb and connecting tube. The flow is regulated simply by means of the usual Hoffman clamp, the rate being kept between 30 and 40 drops a minute. The concentration of sodium bicarbonate in the milk is usually 1 level teaspoon to a quart.

The majority of our patients have experienced little or no difficulty in swallowing and retaining the intra-

gastric tube. A small but significant percentage, however, are apprehensive or have a hyperirritable pharynx. Because of this group it is advisable to institute the drip therapy gradually. Accordingly the tube is left in place for one hour on the first day, for two one hour periods on the second day and for the full interdigestive periods thereafter. During these first days also we have found it advisable to give a soporific (usually phenobarbital $1\frac{1}{2}$ grams [0.1 Gm.]) before the patient retires. Patients with uncomplicated ulcers with mild symptoms learn how to administer the drip therapy to themselves within a few days, so that it can be used at home without the aid of a nurse. Thereafter, patients with mild symptoms may continue their usual daily occupations on the conventional intermittent ambulatory ulcer therapy and take the drip during the night for long periods (even for many months). Patients with moderate or severe symptoms require continuous bed treatment for at least three weeks. Patients with extremely severe symptoms which do not respond to this interdigestive treatment are usually placed on continuous twenty-four hour milk drip therapy without any nutrition besides the 3 quarts of milk so administered each day. Following this, the patient continues the routine described for mild symptoms. Of course all forms of intragastric drip therapy are contraindicated by the presence of an infection of the upper respiratory tract.

THIRTY-THREE OBSERVATIONS

Since the drip therapy was instituted ten years ago some hundreds of patients have been treated by means of it. It is not our intention to describe the cases in detail here. However, 60 of these cases have been studied carefully to illustrate the fact that certain patients with severe ulcers who were refractory to the conventional ulcer treatment (i.e. Sippy) may be relieved by the administration of the drip. Many of the patients were elderly men with histories of ten to thirty-five years of chronic penetrating ulcers. They had frequent exacerbations with severe pain, usually radiating to the back, especially at night. Many had also had complications of previous episodes of gastrointestinal bleeding and were considered to be subjects for surgery. Their gastric acidity figures were high both during the day and during the night. Some had short histories, but progressive intractable pain suggesting penetration with impending perforation. These were treated with the usual Sippy therapy in the clinic or privately, without relief of symptoms, and were consequently sent into the hospital because of the refractoriness. In most cases drip therapy was not begun until all other measures in bed had failed. This was especially true of patients with nocturnal distress, to whom only the drip gave relief. Some of the patients would not accept or could not be given relief by surgery because of age, cardiovascular, pulmonary or neurologic complications or poor general condition. In these instances as well as in those with intractable pain day or night unrelieved by the usual methods of therapy drip treatment was of great value. The rapid and complete disappearance of jejunal, gastric and esophageal ulcers, as evidenced by x-ray examination and gastroscopy, has given striking proof of the value of continuous neutralization of intragastric acidity by the drip method.

All these cases will be described elsewhere in detail but a few of the most striking of them are presented here briefly.

REPORT OF CASES

CASE 1—J K, a man aged 48, had had duodenal ulcer symptoms for eight years, with four hospital admissions during that period. An operation was contraindicated because of progressive muscular dystrophy. The symptoms were refractory to a strict Sippy regimen. He was treated for three weeks by milk drip with excellent result, after which he remained well for two years.

The drip therapy probably saved this patient from a serious surgical hazard.

CASE 2—M A, a man aged 64, was admitted to the hospital for severe pain from a duodenal ulcer eight years ago. Strict Sippy treatment failed to relieve it. Milk drip induced a prompt remission, lasting seven years. A very severe recurrence was unrelieved by one week of Sippy treatment. Following three weeks of successful milk drip therapy he has remained well to date.

Obviously, this elderly emaciated man would have been a poor surgical risk.

CASE 3—I S, a man aged 59, had severe duodenal ulcer symptoms for ten years. During that time he had a massive hemorrhage. Free acidity was 100 units. There was no relief from Sippy therapy in bed. He was given milk drip for two weeks and then aluminum phosphate (amphojel-phosphate) for another week, since which time he has remained well for two years.

CASE 4—J W, a man aged 48 had chronic symptoms of duodenal ulcer for four years. For three months there were severe night pains unrelieved by strict Sippy therapy. Free acidity was 84 units. Milk drip relieved both day and night pains at once. This treatment was continued for five weeks during which time he gained 16 pounds (7.3 Kg). When seen three months later he was still symptom free.

This case illustrates the striking relief of the night pains by the milk drip.

CASE 5—F R, a man aged 38, for fifteen years had duodenal ulcer symptoms including a massive hemorrhage. He was admitted to the hospital for severe continuous pain. Sippy treatment afforded no relief, so a partial gastrectomy was advised but refused by the patient. He was then given the aluminum phosphate drip for three weeks with complete relief of his symptoms. He has remained well for two and a half years.

CASE 6—J G, a man aged 38, for ten years had typical symptoms of gastric ulcer. Free acidity was 78 units and repeated roentgenograms revealed a large ulcer in the lesser curvature which did not change in size throughout a whole year. After one month of continuous severe pain day and night, without relief by Sippy treatment, gastroscopy revealed a possible malignant growth. Aluminum phosphate drip was then administered for three weeks. There was a complete loss of symptoms and in four weeks the large niche had disappeared. He has been observed for two years since then and has remained symptom free with negative roentgen findings.

This case illustrates the great value of drip therapy in distinguishing a benign from a malignant ulcer.

CASE 6—S S, a man aged 67, after twenty years of typical duodenal ulcer symptoms had a gastroenterostomy performed fifteen years ago. Severe, continuous pain during the past five months was unrelieved by strict Sippy therapy. Roentgenography revealed a penetrating jejunal ulcer the size of a 25 cent piece (24 mm). He was placed on milk drip therapy for four weeks day and night and thereafter for another two months on night drip only. His symptoms were relieved promptly on institution of this treatment, the niche disappeared in five weeks. He gained 50 pounds (22.7 Kg) in three months and has remained well for six years.

In view of the fact that recurrent gastrojejunal ulcer usually responds poorly to medical treatment, this is a striking example of the value of drip therapy.

CONCLUSION

We are in harmony with those who are inclined to be skeptical of any new ulcer therapy. It may be expected that the proponents of a new ulcer therapy should demonstrate (1) that it is rational, (2) that it is practical and (3) that it produces prompt and more persistent results than other forms of therapy. We believe, after ten years of experience, that the drip therapy (with milk and sodium bicarbonate or alumina gels) satisfies these criteria.

SUMMARY

1 Continuous neutralization of gastric secretion throughout the day, and especially during the night, is highly desirable in the therapy of peptic ulcer.

2 The continuous intragastric drip therapy between meals and during the night is an excellent method for the adequate control of interdigestive acidity.

3 The method, easily learned, gives the patient a means of self therapy at home for long periods during the night without interfering with his daily work.

THE MANAGEMENT OF FRACTURES INVOLVING THE PARANASAL SINUSES

JOHN J. SHEA, MD

MEMPHIS, TENN.

When a fracture of the facial bones extends into the paranasal sinuses, its management is similar to the surgical procedure followed in radical sinus surgery. In fact the most common complication of these fractures is sinusitis. The basis of treatment is the drainage of the injured sinus and the replacement of the bony fragments to correct the facial deformities thus obtaining a symmetrical orbit and a satisfactory bite.

The ever increasing speed at which man now travels has multiplied the number of instances of fractures of the face, and whenever a paranasal sinus is entered the rhinologist should share the responsibility of its management. These fractures are seldom single and frequently are associated with cranial insults. The general condition of the patient determines the correct time to reduce these fractures. When the injured sinus wall forms a part of the cranial vault, the presence of cerebrospinal rhinorrhea is of importance. Manipulations should be avoided which will open intracranial avenues except as a part of an open operation when any dural tear can be mended.

THE GENERAL CONDITION OF THE PATIENT

Every patient should be hospitalized and observed for twenty-four hours who at the time or immediately after the accident became unconscious. A consultation with a competent neurologic surgeon is advisable before extensive operations are done for the correction of these fractures. The structure of the face is loosely attached to the skull. Blows from above, below or either side will readily separate the facial bones, but blows directed from in front crush the walls of one or more of the sinuses and frequently crack the cranial vault. A desire to prevent facial blemishes should not precipitate a risky early operation. The skin of the face must be cleansed immediately, every particle of foreign material

must be meticulously removed, hemorrhage controlled and the open wounds powdered with sulfanilamide. Transfusions of blood or intravenous administration of isotonic solution of sodium chloride are necessary to prevent shock in the more seriously injured. Not until the patient's general condition warrants the ordeal of an operation should corrective steps be undertaken. Recently the life of a young boy was jeopardized by the early attempt at a plastic operation on facial wounds because a thorough cranial study had been omitted. The lad remained unconscious beyond the usual postanesthetic time, and during the examination for the cause of shock a depressed fracture of the occipital bone was revealed by a roentgenogram.

MAXILLARY SINUS

When the force is exerted on the malar bone, it is displaced and separated from its articulations, and the crushing at times fractures the walls of the antrum.

Fig 1—Method of reducing antral and malar fractures

common occurrence is for the fracture to encircle the base of the malar prominence, beginning in the region of the infraorbital foramen and extending down and around through the thinner posterior antral wall. The facial appearance of such a patient is characteristic, and the deformity depends on the degree of the depression of the malar prominence and the floor of the orbit. The corresponding alveolar process sags, interfering with the bite. If the zygomatic arch is depressed, the coronoid process of the lower jaw may be hampered and at times lock the bite. A roentgenogram in a typical case will present a cloudy antium on the injured side and an inward or outward rotation of the malar bone, with a change in the transverse diameter of the corresponding orbit. A series of planograms will reveal hidden fractures not visible in the ordinary views, and special positions will demonstrate the extent of interference of the movements of the coronoid process.

A study of the normal orbit in the routine postero-anterior view of the sinus will show a line in the outer

third made by the junction of the outer orbital wall and the skull. This line bears a constant relationship to the outer rim of the orbit and may be used to determine whether or not the malar bone has been displaced. The transverse diameter of the orbit is altered in these fractures, being increased in case of outward displacement and decreased in crushing injuries in which the malar bone is rotated inwardly. This relationship and diameter are controls, available for use in determining the correct position of the parts after the resetting of the fractures.

The correction of this type of fracture may be by the traction reduction popularized by Gill,¹ who uses a forceps similar to a large towel forceps. The bone is grasped through the skin, and traction is applied with palpation as a guide. If successful, this method is safe, simple and leaves no scars. The absence of an open wound reduces the possibilities of infection. If the antral wall is badly depressed, the force exerted to replace the fragments must be intra-antral. This may be done through an intranasal antral window with a large Rittor sound. The combination of these two methods is practical, and by the insertion of a No. 14 catheter through the antral window drainage is maintained. The latter procedure is important, as the antrum is usually filled with blood which becomes foul and easily contaminated. If the deformity is extensive, I prefer an open approach to the antrum through a gingival incision, as for a radical antral operation. The fracture may be viewed and displaced fragments rotated or removed. If the parts are accessible to wiring, this is done and there is no better method of maintaining the fragments in position than by wiring. The most serious facial deformity is the result of failure to elevate and maintain into position the floor of the orbit. The sagging of the orbital floor allows the eye to descend, and the expression that the patient views in a mirror is noticeable and at times hideous. The only suicidal attempt because of facial deformities that I have experienced in my series followed the failure of reestablishing a symmetrical orbit. If the parts can be wired into position, this is preferred, for packing is seldom satisfactory.

I have used for a number of years an intra-antral balloon^{2a} filled with water to maintain in position the orbital floor and at times to control severe bleeding. The balloon may remain in place from three to five days, after which the pressure is released. If the hemorrhage recurs or the fragments slip, the pressure may be reinflated after a few hours of rest.

When these fractures are bilateral the ingenuity of the surgeon is taxed. The facial appearance is characteristic—horse face—the descended upper teeth giving the appearance of a poorly fitted denture. Beautiful and practical appliances attached to simple or complicated skull caps have been designed by Kazanjian, Blair,³ Straith,⁴ Adams⁵ and Salinger.⁶ But today the general practice is to wire the fragments by open

methods to fixed parts. In the instance of a bilateral antral fracture with free movement of the upper teeth, the accepted method of many is to attach a wire to either cuspid and bring it through the cheek and fix it to a skull cap. The direction and degree of traction will control the position of the upper teeth, and to

Fig 2—Balloon within the antrum for support of the orbital floor. The balloon was designed by Dr Ferris Smith (Disease and Treatment of the Maxillary Sinus J Michigan M Soc April 1922 p 12)

assure a satisfactory bite the upper and lower teeth are wired into position. Three weeks of this fixation is sufficient time for bony union unless sinusitis develops. The mouth should be kept clean to prevent infections, especially by Vincent's organisms.

A dental insult, as the loss of a tooth within the antrum, is handled after the fashion of radical sinus surgery. If the tooth or root cannot be readily extracted by suction or traction, irrigation should be avoided. It is simpler to make a window through the anterior wall and remove the foreign body with the nail foreign body forceps.

FRONTAL SINUS

The management of frontal sinus fractures depends on whether the fracture involves the inner wall. If the fracture is merely through the inferior or external wall, the deformity is corrected, usually by wiring. The external wounds are cleansed, powdered with sulfamidamide and carefully sutured, for drainage through the nasal frontal duct will suffice. The nasal membrane is treated by vasoconstrictors as during an acute frontal sinusitis to secure free drainage of the sinus by way of the frontal duct. Should this prove inadequate, the drainage will back out of the wound. This promptly becomes evident, and a small rubber drain can be inserted from the outside. When the inner cranial wall is injured, as shown by roentgen examination, a consultation with a neurologic surgeon is necessary to determine the presence of a cerebrospinal rhinorrhea. A quick test for a leak of cerebrospinal fluid is made by having the patient lie face downward on a clean linen handkerchief for ten minutes. If there is a leak there will be a dripping of a clear fluid on the handkerchief which when dried does not crinkle the linen as does the ordinary mucopurulent nasal discharge. The scientific test depends on the ability of the fluid to reduce Fehling's solution.

There are times when the risk of correcting the deformity of the frontal sinus is greater than the cosmetic benefit justifies. Recently, I saw in consultation a lad (R S, aged 16) who while working under a car had his frontal sinus crushed in by being pinned under the axle. The cranial insult was sufficient to warrant a week's observation, and though the fracture apparently transversed the cribriform region there was no leak of cerebrospinal fluid. The extent of the orbital ecchymosis created a fear of injury to the optic nerves. This swelling was so great that any additional post-operative edema would have been disastrous to the youth's sight. After the orbital swelling receded an accompanying nasal deformity was corrected, but the depressed external wall was allowed to remain for future correction.

The dangerous period of the patient with a fracture through the cribriform plate or the posterior wall of the frontal sinus extends through several acute infections of the upper respiratory tract. Cerebrospinal meningitis of the septic type may complicate acute infections of the upper respiratory tract if a fissure is maintained by the invagination of the sinusal membrane between the fragments. The immediate escape of air through similar cracks produces a spectacular roentgenogram, but the condition is rarely important.

F J, a Negro man aged 28, had an extensive traumatic pneumocephalus brought on by blowing his nose after a head injury. The surgical correction of a fracture of the inner wall demands a thorough exposure of the fracture and a search for a tear of the dura. If the latter is encountered it must be repaired or patched, and those involving the cribriform plate are usually hopeless. The mucous membrane about the fracture should be denuded to prevent invagination, which will leave an avenue for the entrance of sinusal infection into the vault. External drainage is necessary even with the protection of chemotherapy.

ETHMOID AND SPHENOID

An occasional fracture of the nasal bone will extend into the anterior ethmoid cells. The correction of the nasal deformity will suffice to reestablish the necessary

Fig 3—Method of wiring separations of the zygoma and frontal bone and fractures of the anterior wall of the frontal sinus.

drainage of these cells. Occasionally a fracture of the base will extend into the sphenoid, but when it does the patient's general condition is so serious as seldom to need surgical assistance. The entrance of foreign bodies, such as bullets, pieces of shrapnel or other foreign materials, are treated according to the indi-

vidual case. It is safer at times to leave a clean fixed particle than to risk the mutilation necessary for its removal.

CONCLUSIONS

The management of fractures involving the paranasal sinuses follows the general principles of sinus surgery. The end results should be a restoration of the features especially to obtaining symmetrical orbits, a reestablishment of good ventilation and drainage of the sinuses, and a satisfactory bite.

ABSTRACT OF DISCUSSION

DR CLAUDE L. STRAITH, Detroit. This problem of facial injuries is becoming of greater importance in every community. For some time I kept a record of such accidents as they came into our office and we found that there was a definite relationship between the position of the patient in the car and the type of injury he sustains. In 50 consecutive cases of facial injury there were only 8 drivers. There were 8 persons who had been riding in the rear seat. The great percentage of victims with crushing facial injuries were riding in the front seat beside the driver. We find that about 70 per cent of these victims are young girls and women who were riding in this "death seat." Typical malar bone injuries occur more frequently on the right side than on the left. Dr. Shea mentioned certain methods of elevating the depressed malar bone and I will describe a simple and satisfactory method. The area is well anesthetized with procaine hydrochloride and a small incision made through the mucous membrane above the molars. A heavy curved instrument is passed up under the malar bone by upward traction almost any malar bone can be elevated into position. Failure to elevate the malar leaves a dropped orbit and flat cheek bone, which is quite a deformity. Dr. Shea mentioned several methods of holding crushed facial bones together. We like to use a silver wire arch bar, fastened securely to the teeth. From a position near the bicuspid teeth another wire is passed up through the cheek and the entire upper jaw suspended by fixing the upper end of the wire to coat hanger wire supports fixed in a plaster head cap. These patients can chew food and keep the mouth quite clean through treatment. For the nasal bones we use a special apparatus which elevates the bridge and produces lateral compression. In crushing injuries to the frontal bone we often drill a hole in the outer table, screw in an ordinary wood screw, leaving the head protruding about $\frac{1}{8}$ inch and from this an elastic band is carried up to a suspension rod on the head cast. As prophylactic propaganda we have been working with automobile companies and have persuaded them to remove the projecting gadgets and cranks from the dashboard or instrument panels, which used to tear faces so badly, and as a further precaution have urged that they incorporate a crash pad in the instrument panel, which I believe would go a long way toward minimizing the type of injuries Dr. Shea has discussed.

DR ROBERT H. IVEY, Philadelphia. The need for thorough cooperation with the neurologic surgeon in cases of severe facial injury cannot be overemphasized, and extensive manipulation of displaced bones in the presence of cranial complications may have serious results. At the same time, when serious displacements exist, particularly of the malar and superior maxillary bones, early reduction is urged whenever it can be done with safety, because, if these fractures are allowed to unite firmly in malposition, satisfactory correction later may be impossible. One frequently sees cases of grave permanent facial deformity with loss of function of the jaws, either because the condition of the patient did not permit early reduction or because in the anxiety over the cranial injury the face deformity was entirely overlooked. For diagnosis of fractures of the upper jaw and malar bones, I rely principally on clinical signs and symptoms. To me x-ray examination of this region is very disappointing, and I have not had much satisfaction from the planograms. In fracture of the malar bone and zygomatic arch the most valuable x-ray information is obtained from a film made with the rays directed down through the vertex to the chin of the patient

resting on the table. This permits easy comparison of the bony outlines on the two sides and also reveals opacity in the maxillary sinus. I do not think it is necessary or advisable in the ordinary fracture of the malar bone with rupture into the maxillary sinus to open into and drain the latter. In the great majority of cases of this kind the blood in the sinus takes care of itself without infection, and the deliberate opening and draining routinely would invite trouble in a certain percentage. This also applies to fractures of the maxilla in which the sinus is involved. In the ordinary depressed fracture of the malar without serious comminution I find that the easiest and least disturbing method of reduction is by a long elevator passed down beneath the temporal fascia through a small skin incision above and in front of the ear, as suggested by Gillies. After reduction by this method the bone usually stays out in position without fixation. In cases with serious crushing of the sinus walls this may have to be combined with an intraoral approach, packing the sinus, bone wiring, and so on.

DR C. C. COLEMAN, Richmond, Va. My interest in fractures of the paranasal sinuses arises from the fact that these fractures may provide an avenue of entrance to infection into the meninges. In fractures of the superior maxilla a cranial or intracranial injury is very common and it is the latter which should receive first consideration. So frequently are cranial fractures associated with fractures of the superior maxilla that in our hospitals such cases come primarily to the neurosurgical service. The rhinologist cooperates in the management of the sinus injury. We try to prevent undue delay in instituting treatment for the injured sinus, but we also try to avoid the error of applying treatment for a local sinus condition before determining the extent of more important associated cranial or intracranial injury. In a paper before this section in 1937 I reviewed paranasal sinus fractures and fractures of the mastoid in association with fractures of the base of the skull. In a two year series in which there were eighty seven fractures of the base there were 15 cases of fracture of the frontal sinus, indicating that fracture of the frontal sinus is often associated with more extensive cranial injuries. Evidences of such injury are found in the unconsciousness of the patient, cerebrospinal fluid leak and occasional pneumocephalus, perhaps more often the diagnosis of cranial fracture may be made inferentially by cranial nerve palsies. The third and sixth nerves are often involved in fracture of the superior maxilla in which there has been an associated fracture of the skull. Diplopia is not an uncommon result. Radical treatment has been advocated for the fracture of the frontal sinus. There may be, as Dr. Shea has said, a cerebrospinal fluid leak which proves there is a connection between the meninges and the sinuses, but it is not always easy to determine the location of the opening in the dura. We have been conservative in the treatment of fractures through the posterior wall of the frontal sinus, even when laceration of the meninges is suspected, particularly since chemotherapy has become available. If a leak persists, however, it may be necessary to repair the opening in the dura through a small frontal flap. The necessity for operation in these cases will be rare with the judicious employment of sulfamide and sulfadiazine. Nearly all such leaks will cease spontaneously. When the proper time comes, and delay of ten days to two weeks may be necessary because of the patient's general condition appropriate treatment of the fractured sinus by the rhinologist should be carried out.

DR M. F. ARBUCKLE, St. Louis. You might be interested in what we are doing with these cases in an army camp. A sergeant came in with about half his scalp gone with the rest of it cut up as though some one had run a knife around his head. He had a fracture through the maxilla, with a downward displacement, so that his mouth could not be shut because the teeth would not line up. He had a skull fracture, loss of the eye and fracture of a leg and an arm and of some ribs. He was unconscious and had bled a great deal. He was put to bed and nothing was done except supportive measures. After several days the fragment of the jaw slipped back into position and remained there. I have been struck with the readiness with which these fragments of jaw or nose or skull will remain in position if they are replaced without much prosthesis. The first principle of treatment is to put these soldiers to bed and do

as little as possible for the first week or ten days, aside from supportive treatment. We do have the neurologist and the internist see them, and the general surgeon, but we never think of extensive corrective measures until they are well out of the woods. The most important single thing in the way of treatment is sulfonamide therapy. We invariably saturate them to the limit with one of the sulfonamides, and it is astonishing how few complications, such as meningitis we see. We have recently discharged a man from the hospital who came in with a fracture through the sphenoid running down into his maxilla, up through the temporal bone, back through it and up through the frontal bone. He was unconscious for eight or ten days. We kept this man quiet and supported him and gave him full doses of sulfathiazole. He was discharged for duty after a month or six weeks.

CARE OF THE AGED

MALFORD W. THEWLIS, M.D.

WAKEFIELD, R. I.

Geriatrics was not spontaneously recognized as a special branch of medicine, like pediatrics, it met with slow response. When Abraham Jacoby gave the first course in pediatrics in 1859, it was coolly received, the medical profession had to wait thirty-seven years for a textbook on diseases of infancy and childhood.

The word geriatrics was coined by Nascher¹ in 1909, and five years later he completed a textbook on diseases of old age,² which went through a second edition in 1916. It was then that Nascher decided to enter the Public Welfare Department of New York City and suggested that I carry on, with his help and advice, this seemed possible.

During the past few years attention has focused on geriatrics, this was logical, since life expectancy was increasing (It has reached 65). In two decades the age group past 60 may exceed the below 10 age group.

A survey of figures in table 1 indicates the shifts in the ratio of children and persons past 60 from 1930 to 1940. Table 2 shows a gradual decrease in the number of children and a substantial increase in the past 60 age group, this survey covers the estimated total population of the United States from 1945 to 1980.

In wartime, when the armed forces absorb a large proportion of the male youth, there is an increasing need for older men who are fit and can till the land or work in offices and factories, replacing selectees. In Germany the elderly and the children often work side by side in munitions plants, while in our country many able bodied older men are perforce idle because they have not yet been fitted into the pattern of total war. In the Ford plant, however, men of 75 are earning and producing, and room is found for persons handicapped by asthma, arterial hypertension or arrested tuberculosis, and even by such gross physical defects as blindness or by loss of limbs. Ford opened the first industrial rehabilitation clinic and paved the way for industrial groups interested in social and economic problems.

MEDICAL CARE OF THE AGED

In 1940 there were about thirteen million persons past 60 in the United States, over nine million of whom were over 65. Few among them are self supporting, and many are dependent on small pensions. Most have surrendered and believe that they can no longer pull

their own weight. Now some hope that Congress will see fit to grant monthly pensions of \$30 to each person past 60, but such an allowance would hardly allow for private medical care if needed. The economic plight of the aged is likely to grow worse.

The state of Washington has a plan for medical care of the elderly,³ the state department of social security is responsible for the programs with \$5,320,000 at its disposal. Hospital care, nursing and appliances are handled by each county welfare department.⁴ Indiana and Illinois also have plans for the medical care of the elderly. West Virginia is experimenting on plans for old age medical treatment, and Iowa has a plan under consideration.

GERIATRICS, A SPECIAL BRANCH OF MEDICINE

Geriatrics may loom large, since social and economic factors may force the medical profession to devote as much time to the aged as to the very young. Undoubtedly there will soon be courses in geriatrics in medical schools, and medical societies will be founded to further the study of diseases of old age. There will be more hospitals and clinics devoted to the care of the aged. Physicians will focus on preventive geriatrics (gerontology)⁵ dealing with senescence (normal old age) and on senility (abnormal old age).⁶

THE APPROACH TO GERIATRICS

A physician genuinely interested in geriatrics does not necessarily work in hospitals and clinics. Some physicians in rural areas are doing scientific work in their own offices which they use as clinics and laboratories. Their necropsies are often painstakingly done and as accurate as those made in hospitals. Necropsies are important contributions to the advancement of geriatrics. Much is learned at the bedside. For every seriously ill old person who consults a physician there are a hundred with simple ailments causing discomfort which may precede actual disease. Physicians are often baffled by simple ailments, and surgeons are disconcerted when forced to treat ambulatory patients without hospitalization, but they must realize that the aged are seldom willing to go to hospitals, they cling to familiar surroundings and to their relatives, and there is no reason why many of them should not remain at home when ill. Unless they are mentally unsound or destitute, one cannot hospitalize against their will. One must be prepared for blood transfusions and intravenous solutions in the patient's home if hospitalization is objected to. A small portable laboratory outfit and portable x-ray apparatus often will make a scientific study possible without hospitalization. When dealing with elderly patients, Rowntree preferred surgical interventions at home whenever feasible.⁷

A physician interested in geriatrics might have a clinic in his office and give the underprivileged the benefit of low fees, thus keeping them off the charity list. Old people often feel that they get more attention in a physician's private office than in an institution. If they are ill at home the geriatrician could visit them for a moderate fee. If physicians adjust their fees to the circumstances of the patient, they will be amply repaid in knowledge gained. Carefully taken case histories and cross indexes are constructive.

The great percentage of victims with crushing facial injuries were riding in the front seat beside the driver. We find that about 70 per cent of these victims are young girls and women who were riding in this "death seat." Typical malar bone injuries occur more frequently on the right side than on the left. Dr. Shea mentioned certain methods of elevating the depressed malar bone and I will describe a simple and satisfactory method. The area is well anesthetized with procaine hydrochloride and a small incision made through the mucous membrane above the molars. A heavy curved instrument is passed up under the malar bone, by upward traction almost any malar bone can be elevated into position. Failure to elevate the malar leaves a dropped orbit and flat cheek bone, which is quite a deformity. Dr. Shea mentioned several methods of holding crushed facial bones together. We like to use a silver wire arch bar, fastened securely to the teeth. From a position near the bicuspid teeth another wire is passed up through the cheek and the entire upper jaw suspended by fixing the upper end of the wire to coat hanger wire supports fixed in a plaster head cap. These patients can chew food and keep the mouth quite clean through treatment. For the nasal bones we use a special apparatus which elevates the bridge and produces lateral compression. In crushing injuries to the frontal bone we often drill a hole in the outer table, screw in an ordinary wood screw, leaving the head protruding about $\frac{1}{8}$ inch and from this an elastic band is carried up to a suspension rod on the head cast. As prophylactic propaganda we have been working with automobile companies and have persuaded them to remove the projecting gadgets and cranks from the dash board or instrument panels, which used to tear faces so badly, and as a further precaution have urged that they incorporate a crash pad in the instrument panel, which I believe would go a long way toward minimizing the type of injuries Dr. Shea has discussed.

DR ROBERT H. IVY, Philadelphia. The need for thorough cooperation with the neurologic surgeon in cases of severe facial injury cannot be overemphasized, and extensive manipulation of displaced bones in the presence of cranial complications may have serious results. At the same time, when serious displacements exist, particularly of the malar and superior maxillary bones, early reduction is urged whenever it can be done with safety, because, if these fractures are allowed to unite firmly in malposition, satisfactory correction later may be impossible. One frequently sees cases of grave permanent facial deformity with loss of function of the jaws, either because the condition of the patient did not permit early reduction or because in the anxiety over the cranial injury the face deformity was entirely overlooked. For diagnosis of fractures of the upper jaw and malar bones, I rely principally on clinical signs and symptoms. To me, x-ray examination of this region is very disappointing and I have not had much satisfaction from the planograms. In fracture of the malar bone and zygomatic arch, the most valuable x-ray information is obtained from a film made with the rays directed down through the vertex to the chin of the patient

resting on the table. This permits easy comparison of the bony outlines on the two sides and also reveals opacity in the maxillary sinus. I do not think it is necessary or advisable in the ordinary fracture of the malar bone with rupture into the maxillary sinus to open into and drain the latter. In the great majority of cases of this kind the blood in the sinus takes care of itself without infection, and the deliberate opening and draining routinely would invite trouble in a certain percentage. This also applies to fractures of the maxilla in which the sinus is involved. In the ordinary depressed fracture of the malar without serious comminution I find that the easiest and least disturbing method of reduction is by a long elevator passed down beneath the temporal fascia through a small skin incision above and in front of the ear, as suggested by Gillies. After reduction by this method the bone usually stays out in position without fixation. In cases with serious crushing of the sinus walls this may have to be combined with an intraoral approach, packing the sinus, bone wiring, and so on.

DR C. C. COLEMAN, Richmond, Va. My interest in fractures of the paranasal sinuses arises from the fact that these fractures may provide an avenue for entrance to infection into the meninges. In fractures of the superior maxilla a cranial or intracranial injury is very common and it is the latter which should receive first consideration. So frequently are cranial fractures associated with fractures of the superior maxilla that in our hospitals such cases come primarily to the neurosurgical service. The rhinologist cooperates in the management of the sinus injury. We try to prevent undue delay in instituting treatment for the injured sinus, but we also try to avoid the error of applying treatment for a local sinus condition before determining the extent of more important associated cranial or intracranial injury. In a paper before this section in 1937 I reviewed paranasal sinus fractures and fractures of the mastoid in association with fractures of the base of the skull. In a two year series in which there were eighty-seven fractures of the base there were 15 cases of fracture of the frontal sinus, indicating that fracture of the frontal sinus is often associated with more extensive cranial injuries. Evidences of such injury are found in the unconsciousness of the patient, cerebrospinal fluid leak and occasional pneumocephalus, perhaps more often the diagnosis of cranial fracture may be made incidentally by cranial nerve palsies. The third and sixth nerves are often involved in fracture of the superior maxilla in which there has been an associated fracture of the skull. Diplopia is not an uncommon result. Radical treatment has been advocated for the fracture of the frontal sinus. There may be, as Dr. Shea has said, a cerebrospinal fluid leak which proves there is a connection between the meninges and the sinuses, but it is not always easy to determine the location of the opening in the dura. We have been conservative in the treatment of fractures through the posterior wall of the frontal sinus, even when laceration of the meninges is suspected, particularly since chemotherapy has become available. If a leak persists, however, it may be necessary to repair the opening in the dura through a small frontal flap. The necessity for operation in these cases will be rare with the judicious employment of sulfanilamide and sulfadiazine. Nearly all such leaks will cease spontaneously. When the proper time comes, and delay of ten days to two weeks may be necessary because of the patient's general condition, appropriate treatment of the fractured sinus by the rhinologist should be carried out.

DR M. F. ARBUCKLE, St. Louis. You might be interested in what we are doing with these cases in an army camp. A sergeant came in with about half his scalp gone with the rest of it cut up as though some one had run a knife around his head. He had a fracture through the maxilla, with a downward displacement, so that his mouth could not be shut because of the teeth would not line up. He had a skull fracture, loss of an eye and fracture of a leg and an arm and of some ribs. He was unconscious and had bled a great deal. He was put to bed and nothing was done except supportive measures. After several days the fragment of the jaw slipped back into position and remained there. I have been struck with the readiness with which these fragments of jaw or nose or skull will remain in position if they are replaced without much prosthesis. The first principle of treatment is to put these soldiers to bed and do

as little as possible for the first week or ten days, aside from supportive treatment. We do have the neurologist and the internist see them, and the general surgeon, but we never think of extensive corrective measures until they are well out of the woods. The most important single thing in the way of treatment is sulfonamide therapy. We invariably saturate them to the limit with one of the sulfonamides, and it is astonishing how few complications, such as meningitis, we see. We have recently discharged a man from the hospital who came in with a fracture through the sphenoid running down into his maxilla, up through the temporal bone, back through it and up through the frontal bone. He was unconscious for eight or ten days. We kept this man quiet and supported him and gave him full doses of sulfathiazole. He was discharged for duty after a month or six weeks.

GERIATRICS, A SPECIAL BRANCH OF MEDICINE

Geriatrics may loom large, since social and economic factors may force the medical profession to devote as much time to the aged as to the very young. Undoubtedly there will soon be courses in geriatrics in medical schools, and medical societies will be founded to further the study of diseases of old age. There will be more hospitals and clinics devoted to the care of the aged. Physicians will focus on preventive geriatrics (gerontology)⁵ dealing with senescence (normal old age) and on senility (abnormal old age).⁶

THE APPROACH TO GERIATRICS

A physician genuinely interested in geriatrics does not necessarily work in hospitals and clinics. Some physicians in rural areas are doing scientific work in their own offices which they use as clinics and laboratories. Their necropsies are often painstakingly done and as accurate as those made in hospitals. Necropsies are important contributions to the advancement of geriatrics. Much is learned at the bedside. For every seriously ill old person who consults a physician there are a hundred with simple ailments causing discomfort which may precede actual disease. Physicians are often baffled by simple ailments, and surgeons are disconcerted when forced to treat ambulatory patients without hospitalization, but they must realize that the aged are seldom willing to go to hospitals, they cling to familiar surroundings and to their relatives, and there is no reason why many of them should not remain at home when ill. Unless they are mentally unsound or destitute, one cannot hospitalize against their will. One must be prepared for blood transfusions and intravenous solutions in the patient's home if hospitalization is objected to. A small portable laboratory outfit and portable x-ray apparatus often will make a scientific study possible without hospitalization. When dealing with elderly patients, Rowntree preferred surgical interventions at home whenever feasible.⁷

A physician interested in geriatrics might have a clinic in his office and give the underprivileged the benefit of low fees, thus keeping them off the charity list. Old people often feel that they get more attention in a physician's private office than in an institution. If they are ill at home the geriatrician could visit them for a moderate fee. If physicians adjust their fees to the circumstances of the patient, they will be amply repaid in knowledge gained. Carefully taken case histories and cross indexes are constructive.

A small town general practitioner is in a favored position because continuous clinical studies are possible. City practice is often transient and seldom enables one to watch families as closely as it is possible in a smaller community where heredity and environmental factors are known, the influences of those factors on several generations are often obvious.

No specialty in medicine can be approached as easily as geriatrics. But, to be successful a geriatrician must be genuinely interested in the elderly and willing to study his patients thoroughly. He must not overlook pathologic changes in the aged and must resist the temptation to restore the old to a state normal to maturity.⁸ They must function at their own level. An understanding of the senescent organism is necessary to treat elderly patients with some degree of success. Overenthusiastic treatment must be avoided. The usual result of overtreatment is a high mortality rate.⁹

PRECLINICAL MEDICINE AND GERIATRICS

Preclinical medicine is a logical approach to the prevention of diseases of old age. It deals with pathologic processes likely to occur, such as peptic ulcer, diabetes mellitus, pernicious anemia, arterial hypertension and arterial degeneration. The accompanying chart shows the most common causes of death in the various age groups past 50 and proves the necessity of focusing on these diseases.

Preclinical medicine includes a study of premature degenerative changes. If these can be determined, it may become possible to eliminate influences which hasten disintegration. The goal of preclinical medicine is the study and interpretation of preclinical states, disease soils, constitutional factors, conditioning periods and disease tendencies.⁹

The principles of preclinical medicine clearly apply to persons in their late forties and early fifties. Preclinical studies should be done early enough to allow timely intervention, since late intervention is seldom successful. Preclinical therapy can attack the disease "soil" long before the symptom stage is reached.

The process of deterioration which is called aging is hastened or retarded by two dominant factors, heredity and environment. From the preclinical standpoint they are certainly the most significant.

A diagnosis of specific vulnerability to disease is based on a study of the patient as a whole and includes a study not only of the hereditary background but of constitutional types, racial factors, intellectual equip-

ment, racial adjustment, reaction to climate, occupation and past diseases. Careful history taking is as essential and necessary as a thorough physical examination.

Preclinical medicine is closely linked with geriatrics and goes a step further than preventive medicine, which deals with the prevention of communicable diseases. As stated before, preclinical medicine deals with pre-disease states—the "soil" on which disease develops. Since many of these disease "soils" are not detected until later in life and are a result of hereditary and environmental influences, they often appear in the geriatric period of life. Many persons do not consult a physician for a check-up until they reach the age of 50. Thus the geriatrician becomes a preclinician.

PREVENTIVE GERIATRICS

The actual prevention of diseases of old age while in their incipience is covered by preventive geriatrics. Industrial medicine is helpful, and of course the general practitioner has rare opportunities to prevent disease. The early treatment of precancerous dermatoses seldom fails. The person with diabetes is told how to avoid complications. Warning against such common hazards as slippery floors, sliding rugs and alking on slippery pavements may prevent fractures. Adequate liver therapy for pernicious anemia may halt degenerative changes in the spinal cord. Avoidance of sudden strain (lifting heavy objects, shoveling snow, running for a train) may postpone an attack of coronary thrombosis. Early diagnosis of gastric lesions by gastrophotography and gastroscopy is important. Gastrophotography is an effective office procedure which is not too exhausting to the aged patient.

Many disagreeable conditions may be avoided through a timely removal of foci of infection. Pneumonia may be prevented by the use of sulfridazine for severe infections of the upper respiratory tract. Chemotherapy may save elderly persons who are suffering from genitourinary and other infections. Tuberculosis is not rare in old age, and its prevention is necessary in senescence.

Incidence of common causes of death in persons past 50. Figures taken from Vital Statistics Special Reports 11-2 1941.

ment in childhood. General hygienic measures, mental hygiene and proper nutrition are also important in advancing years. These are only a few of the countless preventive measures which the practitioner may apply in the course of ordinary medical practice.

SURGERY OF THE AGED

Prolapsus uteri which is not causing much discomfort at the age of 50, if untreated, may incapacitate the patient at the age of 70. The person who has gallblad-

8. Thewlis Malford W. The Care of the Aged (Geriatrics) ed 4, St. Louis C. V. Mosby Company 1942.
9. Thewlis Malford W. Preclinical Medicine Baltimore Williams & Wilkins Company 1939.

der disease at the age of 50 and postpones surgical intervention is unwise. Sooner or later these diseases cause discomfort and in more advanced life an operation may frighten a weakened patient or nervous relatives. Corrections in early senescence are advisable.

A more optimistic attitude toward surgical intervention in the aged is to be hoped for. Records show that major operations on persons ranging in ages from 80 to 100 often have been successful. One should not hesitate to operate on old persons if there is a chance of prolonging life and restoring comfort. Many elderly patients suffer exceedingly from gallstones, prolapsus uteri, brain tumor, cancer, hypertrophy of the prostate gland and a number of other diseases. Should they be denied the relief surgery offers? It is interesting to watch elderly patients whose every organ seems diseased undergo a major operation and live usefully several years after.

Geriatrician and surgeon should, of course, cooperate. The geriatrician should study hepatic and renal functions in all patients. Clinical densimetry will help to determine whether subclinical edema is present. Blood transfusions may be required, but if the patient is carefully conditioned before the operation they may not be necessary. Usually, but not always, an elderly patient does better if he is out of bed on the second or third day following operation. Careful study should be given to nutrition and a normal diet resumed as soon as possible. A geriatric nurse should be in attendance.

An experienced surgeon endowed with some degree of healthy optimism based on justified self confidence is most successful with the aged. He understands the senescent organism as well as preoperative and post-operative requirements, he is "in and out" with as little tissue damage as possible, and he selects an anesthetist who has had experience in geriatrics.

CONCLUSIONS

It is necessary to prevent premature deterioration and to give the aged intelligent medical care. They should function at their own level, if the geriatrician bears this in mind, he will not find it difficult to treat them. Early detection of abnormalities and their correction, whenever possible, and timely surgical intervention, when indicated, have prolonged useful lives. Old people, when healthy, can serve as substitutes for younger men serving in the armed forces. Physicians who give them proper medical care are indirectly contributing to the war effort.

ABSTRACT OF DISCUSSION

DR LUCIEN STARK, Norfolk, Neb. Geriatrics will soon become an important phase of the practice of medicine. With conditions as they are, we shall care for the children and the aged; the rest of our population will be cared for by that branch of the armed services in which they are serving. In the treatment of older people, our problem is not to overtreat them. One cannot hope to reconstruct or rehabilitate the aging blood vessels, secretory mechanisms and musculature so that they will be better than good. It cannot be done. One cannot restore the lumen or the elasticity of the blood vessels. The secretory mechanisms are failing because of poor blood supply and damage from the untoward incidents of life. Musculature is failing because of natural wear and tear as well as from defective nutrition, and this musculature cannot be rebuilt. Successful treatment of the aged must be based on getting them to adapt themselves to the condition of their blood vessels, musculature and secretory mechanisms rather than making these things conform to the ideas of the patient. Excessive use of coffee and tobacco are not the best thing for blood vessels, but to take coffee and

tobacco away from some old persons who have used them for a long time makes them think they are being punished rather than being treated. They are far better off to continue their use and to take enough alcoholics to dilate their vessels and at the same time give them a little stimulation. Alcohol not only is a stimulant to these people but also acts as a narcotic and serves to make life a little more bearable and enjoyable for those who are on the downhill side. If they are deficient in hydrochloric acid, give them enough acid to make up the deficit so that their proteins will be properly split and they can eat whatever protein they want without a gastric upset. If they have insufficient bile to handle fats properly there are many excellent preparations of bile which they can take so that there will be no resulting fatty indigestion to make them miserable. The nutrition and metabolism of these older people must be based on replacement therapy in order that they can be comfortable and enjoy their declining years. The lengthening of the span of life, the taking away of our young and middle aged group of people, make it necessary that we learn to care for the aged in the most sensible and scientific manner.

DR WINGATE M. JOHNSON, Winston-Salem, N. C. Years ago an elderly friend made an observation that one grows older not by an inclined plane but by steps. I have found Dr Thewlis's book on the care of the aged fascinating, as he pointed out, the proportion of elderly people in the general population is increasing yearly. The specialty of geriatrics may ultimately equal, if not surpass, pediatrics in importance. Indeed, the declining birth rate caused the American Academy of Pediatrics in June 1938 to adopt resolutions in favor of extending the limit of that specialty from birth almost to the voting age. If this century's downward trend in the birth rate continues, a future meeting of the academy may vote to take the second childhood within its province. Certainly there are many problems common to the two extremes of life. A few points in Dr Thewlis's paper I should like to emphasize. The first is the danger of overtreatment. The observation by Hippocrates that "all great changes, either one way or another are hurtful" applies particularly to older people. I do not agree with Dr Thewlis that "the aged are seldom willing to go to hospitals." A great many find a visit to the hospital something of an adventure and if the nurses and resident staff are tactful in dealing with them, often they will look back with pleasure to their hospital experience. I agree with Dr Thewlis's views on surgery for older patients. Often a comparatively simple operation gives such patients a new lease on life and it is quite true that they stand operations surprisingly well. Many a man has had the last fourth or third of his life made miserable by having to wear a truss for a simple hernia that could have been repaired in half an hour. Many a woman has endured the misery of a constant backache and sometimes the embarrassment of a constant dribbling of urine that might have been relieved by a perineal repair. I should like to offer the suggestion that we encourage these patients to develop wide interests and to cultivate hobbies in the present period.

DR GEORGE M. LEVITAS, Westwood, N. J. The physician should recognize his responsibility to the older patients. In my state and particularly in my county a number of convalescent homes have been established in recent years for the care of the aged. This has followed a demand for accommodations for those who cannot find the necessary attention at home. While the county home is provided with suitable laboratory facilities and social opportunities the convalescent homes privately managed are nothing more than wards for old people. The old folks sit around smoke excessively, knit or do anything they can find to kill time. There is no organization for pleasure or physical effort. Because we have done everything to make people live longer we should make their lives pleasant, comfortable and worth while. We should, as a profession, provoke in our lawmakers an effort to effect such a program. All over our state there are keep well stations for the young, who probably would do just as well without official interference, but nothing is done for the older people. Recently an aged woman fell and fractured her femur. At the hospital the orthopedist applied a cast to the pelvis and to both the fractured and well lower extremities. After six weeks of immobilization the cast was removed, it was observed that there

was complete union and good muscle tone in the injured leg but that the uninjured was completely atrophied. There was a foot drop, and the patient was able to move about best with the injured member. The fracture had provoked an optimum supply of blood to meet the needs of repair at the expense of the normal leg, which suffered a minimum of blood supply. This may establish the fact that old people will develop more or less atrophy and dysfunction and will die much earlier without obtaining any benefit from our medical attention unless we provide systematic and scientifically controlled entertainment and exercise.

DR M W THEWLIS, Wakefield, R I. I am glad Dr Johnson brought up the question of hospitalization. It is better if aged patients can be sent to hospitals, but there are a great many who won't go. The general practitioner must be prepared for those patients who refuse hospitalization. Regarding the future of geriatrics, the estimated number of children from infancy to 9 in 1945 is 21,446,000, compared with 15,193,000 persons 60 and over. The estimated figures for 1960 are 20,680,000 up to the age of 9 and 21,584,000 persons who are 60 and over, for 1980 the figures are 19,249,000 from infancy to 9 and 31,218,000 for persons who are 60 and over.

CANCER CONTROL IN WESTCHESTER

GEORGE C ADIE, MD

Director of Surgery, Grasslands and New Rochelle Hospitals
AND

H R CHARLTON, MD

Attending Gynecologist and Obstetrician, Lawrence Hospital, Bronxville, N Y; Director, American Society for the Control of Cancer

BRONXVILLE, N Y

This paper presents a discussion of an actual practice directed toward the control of cancer in Westchester County, N Y, population, half a million, an experiment the virtues of which have created considerable interest abroad while developing within the county great comfort to members of families of low income and help to doctors in the cure of patients usually encountered in distressing circumstances.

In 1928 Dr Howard Canning Taylor Sr, then president of the American Society for the Control of Cancer, conceived the idea of extending the activities of that organization beyond cities possessing machinery for cancer education to sections of the country having no such equipment, hoping to develop a more optimistic attitude toward the outcome of the cancer diseases and to spread to adult populations such educational aids as might lead toward a recognition of the threat of cancer on the appearance of early symptoms. With this object in view he persuaded us to attempt such an experiment.

In many ways, Westchester was an admirable proving ground. The intelligence of its people was better than average, and its per capita wealth at that time was high. It contained several cities of more than forty thousand inhabitants and supported one thousand doctors and fifteen hospitals. Its southern boundary was New York City with all that such a relationship signified in advantages of consultation and help. The term "cancer," though usually discreetly hidden by the phrase "a long illness" was more freely used than in many other communities.

It might interest one to speculate on one's course of procedure if presented with a problem such as we found facing us. Between the Hudson River and Long Island Sound, in our territory, over five hundred people died each year of cancer and approximately two

thousand were continuously ill of the cancer diseases. We were to learn that of this two thousand about five hundred were members of low income or completely dependent families. A quick survey showed that no agencies, no hospitals, no clinics were giving special consideration to cancer patients, nor were accommodations available for their care. No recognition was devoted exclusively to the cancer problem except by a group of Catholic Sisters who, at Rosary Hill in Hawthorne, carried on an establishment where patients in the terminal stage might die in peace.

Believing that the cancer problem demanded the consideration primarily of medical men, an exclusively medical committee except in the posts of treasurer, attorney and executive secretary was formed. From hospital staffs in various parts of the county, twenty men were invited to constitute this group, which arrived at the following general conclusions:

Cancer is not an utterly hopeless disease, because 40 per cent of all cases are vulnerable to early attack, provided the forces of cancer cell destruction are intelligently selected and directed.

Forty per cent of the one hundred and fifty thousand who die annually from cancer in the United States, sixty thousand, represents a human fraction worthy of medicine's greatest effort.

Medical schools having failed to place adequate accent on early cancer diagnosis, graduates frequently are insufficiently trained to recognize the disease in its curable stages and are careless about mistaking on immediate expert care. Lay groups are ignorant of the import of early signs and symptoms which should be part of their common knowledge.

It is possible within limits of half a million to develop ways and means to stimulate doctors, to educate laymen and to arrange that the necessary facilities and the tools of reconstruction be offered to both. Without facilities for adequate clinical care, there is no value in education.

Success for any cancer control effort may not be claimed by any organization until, progressively over the years, the cancer mortality curves are bent downward in populations receiving adequate cancer service.

Of conclusions such as these, a springboard was constructed. Out of these the Westchester plan was evolved. A first step was to establish headquarters on a busy thoroughfare in the more congested part of the county, for location is as important to cancer offices as is Fifth Avenue to Tiffany. We have learned the desirability of dignified publicity so that the term "cancer" shall be as familiar as that of other common threats to life, that exhibits of radium therapy equipment, of photographs, of x-ray material and samples of cancer literature must be displayed so as to become well known to people who are to be approached for support of control work.

In the home of the first county cancer committee to be launched in the United States, with an executive secretary and an assistant, we spread our plan on paper and started a fifty year experiment, embracing primarily the following steps:

1 To persuade the members of the Westchester County Medical Society to consider us an agency for the general good, to use us for the purpose of cancer consultation and assistance, and to cooperate with us in an effort to establish a high grade of cancer care for low income and indigent cancer patients throughout the county.

2 To assist hospital superintendents, boards of governors and staffs to develop cancer services to meet the requirements of the American College of Surgeons

3 To advertise clinics to doctors and, through the daily papers, to the public, and to supply such clinics with efficient secretarial and adequate professional nursing service, uniform records in duplicate and their patients with follow-up care

4 To seek to reach at frequent intervals as many men and women as possible by informal talks and formal lectures in clubs, fraternal organizations, factories and churches by car cards, newspaper advertising, short articles and dissemination of available literature, and by intensive campaigns against cancer in special organs of the body

5 To supply hospitals supporting cancer clinics with current literature relating to cancer and with important basic textbooks, to arrange lectures for all doctors on all known phases of cancer, including instructions covering various agencies available for its control

6 To purchase radium and establish a radium bank, with equipment necessary for the use of this element under direction of clinic chiefs, preparations ordered through them to be assembled, delivered and collected, and accurate records kept of these transactions

7 To arrange for the transportation of patients when necessary

8 To develop a card index and mailing list for use in annual drives for money to support the developing program

As the years passed, we received an astonishing support. An increasing number of doctors throughout the county gave the committee a chance to help in difficult cancer problems, and the cancer office became a clearing house for the consideration of complexities developing about the disease.

As departments of general science, particularly of biology, developed with increasing speed in our schools it was realized that a vast field lay virgin, full of promise, all about us. That boys and girls, 14 or 15 years of age, offered a unique opportunity for the dissemination of cancer information.

Pioneering in this field, we introduced cancer teaching developing an outline for a textbook, "Youth Looks at Cancer," for distribution to students in departments of biology. This was inaugurated in the Westchester cancer office, assisted by the department of biology in the Scarsdale High School, and Helen R. Steward, M.A., Teachers College, New York City, was engaged to elaborate and correlate our information in textbook form. On its jacket are illustrations of student groups at Sarah Lawrence College and the medical department at Yale. Reactions to this book indicated great eagerness for cancer information.

Limited to departments of biology, "Youth Looks at Cancer" failed to reach a sufficient number of students. To correct this defect, we introduced "Detectives Wanted," an interesting and very inexpensive script which we plan to place annually in every school, on the desk of every boy and girl in their fourteenth or fifteenth year. When it is realized that there are two million children of that age in the schools of the country, with a potential four million parents or guardians, it is easy to see how extensive and important such an approach may become. Its estimated cost for the United States would be twenty thousand dollars approximately four hundred dollars annually per state.

With an office force organized so that all business pertaining to committee activities might receive prompt attention, the Westchester Cancer Committee in 1929 launched its initial campaign for funds by mail. Forty-three thousand persons were solicited. Ten per cent responded, and we received \$17,442, an average contribution of \$4.13. In 1941, 77,132 persons were solicited, and 13,887 people contributed \$29,784, an average of \$2.14 per person.

In addition to the educational, publicity and financial program, it became necessary to develop a medium for the actual care of patients. Various hospital groups and local medical societies were visited and the program was explained. This resulted in the early establishment of three clinics. Now there are eight, six of which have been approved by the American College of Surgeons.

When we began, there was not a sufficient number of surgeons trained in cancer diagnosis and treatment to man the clinics, but in each group one or two had a special interest in malignant disease, others were anxious to learn, and through the years associates have become reasonably expert.

Each clinic group consists of four or more doctors: a pathologist, a radiologist versed in roentgen and radium therapy, an otolaryngologist and a general surgeon. In most instances intern and resident staffs assist in history taking, securing biopsies and examining patients. Committee secretaries record essential data obtained by historians from each patient at every visit and forward dictated letters to physicians who have referred patients. Copies of such data are filed in the central office, where uniform records are kept of every patient attending the various clinics of the county. Committee nurses assist patients and doctors during the clinic sessions and visit patients at home when so directed, giving personal attention to and instruction for home care, arrange for the return of patients and make essential follow-up calls. Nurses own and drive motor cars, the running costs of which are assumed by the committee.

Each new case becomes the subject of consultation by the clinic group and a plan for treatment is devised. Return cases are carefully reviewed and accurate progress notes entered on records. Members of each group learn to work harmoniously, differences of opinion are respected and expressed ideas are given an opportunity for evaluation.

At intervals, all records pertaining to a certain organic system are reviewed, treatment and results are correlated, errors are discovered and corrected, and from the information obtained comparisons are made with others' results so that a constant improvement in dealing with the disease is attained.

In 1936 the committee conducted a breast cancer campaign, part of which consisted in sending each doctor in the county pertinent facts regarding the disease and calling the attention of the public to breast inspection by a distribution of one hundred thousand pamphlets, by letters and newspaper articles, covering certain features which a lay person could readily understand. As a result, there occurred in the clinics and in private offices a decided increase in the number of women who presented themselves for breast examination. Such educational work is frequently repeated, so that now few women hide a lump in the breast until treatment has become hopeless. Malignant disease in other organs of

the body has been publicized, always resulting in a notable increase in clinic visits

Three hundred and eight mg of radium owned by the committee is available without charge, and roentgen therapy in many instances is paid for from committee funds. The clinics provide a consultation service for physicians practicing in sections of the county where adequate facilities for cancer diagnosis are not available, and patients formerly regarded as in a hopeless condition are now given a chance for a longer and more agreeable life.

There is still too long an elapsed period from the time symptoms first appear until the patient seeks aid, but patients with early cancer are now applying for advice more frequently, a factor of paramount importance in securing a successful outcome. If any measure of cancer control is to be gained, the life of the cancer shortened and the life of the patient extended, we must bend all our efforts to persuade physicians and the public to be on the alert for the first signs and symptoms of malignant disease in all parts of the body.

Having passed successfully through a depression and now strong in the midst of war, we know that the work of the committee is firmly established. Through ethical practice in the office and the clinics we enjoy the interest of the public, and our place in the esteem of doctors is indicated by the yearly endorsement of committee services by the Westchester County Medical Society. What we have done can be accomplished by many other groups of medical men, and thus the poor of each state relieved of a great mental, physical and financial burden.

Looking back to 1929, it is evident that Dr. Taylor's desire was for a greater dissemination of cancer information. It is fair to say that his idea was confined to an increase in adult education and that the American Society in 1928 had no thought of being involved in the clinical care of cancer patients and had never conceived the idea of including school children in any publicity concerning cancer or of introducing formal cancer teaching in departments of biology and general science in any school curriculum. These factors were born of the Westchester experiment.

89 Pondfield Road

The Rising Generation in Medicine—At no time is it more important to instill into the student mind those high principles which for so many years have guided the practice of medicine. There is, I fear, a growing tendency among students today to regard medicine purely from a materialistic standpoint. Even before the war many of the newly qualified, anxious to convert their acquired knowledge into terms of solid cash, rushed into contract or panel practice without holding any hospital house appointment whatsoever. Since the war the shortage of medical personnel has led to a greater demand for the newly qualified student, and the high fees now paid to temporary locums and assistants cannot but be harmful in the future when the period of present cheap money is past. Another present day aspect of medical student life which personally I much regret is the innovation of political student societies. It is a tradition of British medicine, as it is of the British Red Cross, that our service is independent of political creed. The doctor should be entirely impervious to political influences. His concern is with the great essentials of birth, life and death, which transcend all other considerations, and he should resolutely turn his back to the rival claims of political factions both at home and abroad.—Whitehouse, Sir Beckwith (president of the British Medical Association), *The British Tradition of the New Outlook*, *Brit M J* 2 357 (Sept. 26) 1942.

Clinical Notes, Suggestions and New Instruments

THROMBOPENIC PURPURA COMPLICATING PREGNANCY

TREATED BY SPLENECTOMY RESULTING IN CLINICAL CURE AND FOLLOWED BY THREE FULL TERM PREGNANCIES

ADRIAN V. URBANSKI, M.D. AND CYRIL I. HUTNER, M.D.
PERTH AMBOY, N. J.

Thrombopenic purpura complicating pregnancy is a rare condition and carries a high mortality. Rushmore¹ in 1925 made a thorough review of the literature on the subject and collected a total of 47 cases. A report by DeSaussure and Townsend² disclosed 55 cases up to 1935, and of the total of 52 cases in which the final results were known there was a mortality of 55.7 per cent.

Sanford, Leslie and Crane³ in their review of the literature listed 11 cases in which the fetus also showed a purpura similar to the mother's and they added a case of their own. Rushmore quoted a case of Dohrn's in which the fetus exhibited petechiae similar to the mother's, one of Greenhill's in 1923 in which there was a recurrence of purpura in a succeeding pregnancy and one of Vignas and Strassme's in 1921 in which the purpura recurred in three successive gestations during a period of ten years.

In 1916, at the suggestion of Kaznelson, Professor Schloffer of Prague performed the first splenectomy for thrombopenic purpura.

Our case parallels the characteristic symptoms of purpura of the platelet type as enumerated by Mosher.⁴

REPORT OF CASE

History—Mrs. M. V. since the age of 14 had a tendency to bruise easily, the slightest trauma to the skin being followed by ecchymosis. There had also been prolonged bleeding following small cuts of the skin. She had numerous attacks of epistaxis, especially during the winter, at which time they were related to attacks of choryza. After the extraction of teeth she always had severe hemorrhages that had to be controlled by packings. After brushing her teeth she would have some bleeding from the gums. Her menstruations as a rule were of 1 week's duration and the amount was excessive.

There was no history of allergic, traumatic or hereditary disease. She had measles, chickenpox, pneumonia at the age of 4 years and influenza in 1918. She had never had rheumatic fever, tonsillitis or chorea.

On Dec. 11, 1926, she was admitted to the Perth Amboy General Hospital in the medical service for severe epistaxis. She remained in the hospital nineteen days.

On Feb. 13, 1931, she was again admitted to the hospital with the following history. She had been married a year and a half. She had no children. Her last menstrual period had been on December 20 and had resumed on January 31 and had not stopped for the past twelve days. On admission she was in an almost exsanguinated condition with considerable air hunger. Her pulse was 140 and of poor quality. Examination of the blood revealed 1,580,000 erythrocytes, 11 per cent hemoglobin (Sahli), 5,400 leukocytes, 60 per cent polymorphonuclears and 40 per cent lymphocytes. The erythrocytes showed polychromatophilia, poikilocytosis and normoblasts. Examination of the urine was essentially negative. She was given a direct blood transfusion of 500 cc. of blood. There was a definite improvement but she continued to have slight bleeding. Daily blood examinations revealed a slow rise in the red blood cell count and in the hemoglobin content. On February 26, thirteen days after admission, the red blood cell count was 1,890,000 and the hemoglobin 28 per cent (Sahli). The following day another blood transfusion of 500 cc. of blood was given and the following day the red blood cell count was 2,610,000 and the hemoglobin was up to 39 per cent.

4. Mosher, G. C. The Complication of Purpura with Gestation. *Surg. Gynec. & Obst.* 36: 502 (April) 1923.

On March 3 the coagulation time was four minutes and the bleeding time was eight minutes, the platelet count was 45,000, the red blood cell count was 3,200,000 and the hemoglobin was 50 per cent. There was a gradual rise in the platelet count, and on March 16 the count was 50,000 while the red blood cell count arose to 3,300,000 and the hemoglobin level to 48 per cent. During her stay in the hospital and twenty seven days after admission she had a profuse epistaxis that required repeated nasal packings to control. She left the hospital after five weeks and at the time of her discharge the red blood cell count was 3,410,000 and the hemoglobin 50 per cent.

Two years later, according to her history, she had a miscarriage with some hemorrhage that was controlled by uterine packing. She was treated at home.

On Aug 2, 1935 at the age of 25 she was again admitted to the hospital in the obstetric service at full term with a breech presentation. On admission there was slight edema of the fingers and arms, slight bleeding from the gum margins, petechial hemorrhages and larger ecchymotic areas in the skin. The systolic blood pressure was 135 and the diastolic pressure was 100 mm of mercury, the pulse was 72 and the temperature was 99 F. Fetal heart sounds were present in the right lower quadrant. The laboratory findings were erythrocytes 5,590,000, leukocytes 19,400, hemoglobin 95 per cent, platelets 50,000. The Wassermann reaction was negative. Coagulation time was three and one-half minutes, bleeding time eight minutes, blood nonprotein nitrogen 33 mg and blood sugar 115 mg. The tourniquet test was positive.

During the second stage of labor she complained of numbness of the fingers and toes and suddenly she went into a comatose state with the pulse barely perceptible, followed by clammy twitches of the arms and legs. The fetus was rapidly delivered without any laceration or postpartum hemorrhage. There were no convulsions. She was given intravenously 1,000 cc of 10 per cent dextrose in isotonic solution of sodium chloride and her immediate postpartum condition improved.

Gross Examination of the Fetus—The fetus was a well formed normally proportioned stillborn male baby of approximately 7 pounds (3,175 Gm.), generalized petechial hemorrhages of the skin and a large scrotal hemorrhage were present. In the brain there were subarachnoid hemorrhages chiefly at the base, the appearance was normal on cut section and the ventricles were clear. In the chest the pleural cavities were clear, the lungs had petechial subpleural hemorrhages and on cut section the lungs presented a normal appearance. In the heart were petechial subpericardial hemorrhages. The thymus showed surface hemorrhages. The abdomen showed no free fluid. The liver was a deep purple and uniform in appearance on cut section. The spleen was similar to the liver. The stomach and intestine were normal. The kidneys were normal in size and shape but on cut section revealed hemorrhages in the renal pelvis. The adrenals and bladder were normal. The testicles were hemorrhagic. Sections for microscopic study, unfortunately, were lost during the remodeling of the laboratory, and reports are therefore not available.

Postpartum Course—The seizure that the mother had apparently was a complication of the purpura and not eclampsia. A day after delivery the mother's purpura increased and there was a slight swelling of the hands. The blood pressure was 135 mm of mercury systolic and 80 mm diastolic. Her general condition seemed good. Three days after delivery the lochia was normal. There was severe ecchymosis of the vaginal walls and around the urethra. Examination of the blood at this time showed erythrocytes 4,480,000, leukocytes 18,000, hemoglobin 59 per cent, coagulation time three and one-half minutes and the bleeding time eight minutes. A catheterized specimen of urine was amber, clear, acid, with a specific gravity of 1.017, albumin 3 plus, no acetone, few granular casts, no pus cells and many blood cells. Her antepartum urines had been normal. Six days post partum the purpuric spots showed evidence of fading. Nine days after delivery her general condition was good and she left the hospital.

On August 21 nineteen days post partum and ten days after her discharge from the hospital, she was readmitted to the hospital. On admission she was pale and gave a history of

profuse vaginal bleeding for the past twelve or eighteen hours. The temperature was 100.4 F and the pulse rate 120. There was a functional (ischemic) murmur at the apex of the heart which was not transmitted. Examination of the blood on admission showed erythrocytes 3,880,000, leukocytes 11,200, hemoglobin 65 per cent, polymorphonuclears 70 per cent, lymphocytes 29 per cent, eosinophils 1 per cent and platelets 25,000, the red cells showed polychromatophilia and some basal stippling, the bleeding time was ten minutes and the coagulation time was three and one-half minutes with a non-retractile clot. The urine was clear in appearance and alkaline, with a specific gravity of 1.005, albumin 2 plus, no casts, no sugar or acetone, few pus cells and no blood.

She was given repeated direct transfusions of 500 cc of blood. She continued to have uterine bleeding, and repeated uterine packings did not control the bleeding. Repeated blood counts were done and they showed a gradual drop in the red cell count to 2,320,000 and the hemoglobin dropped to 40 per cent. The beneficial effect of the blood transfusions were short lived. The day after a transfusion the red blood cell count would rise by 100,000 but the hemoglobin content did not rise or would be lower than before the transfusion, and evidently this was due to the continuous oozing of blood from the uterus. On admission the platelet count was 25,000. The following day it dropped to 10,000 and remained around 10,000 until she was operated on. On both arms in the areas in which she was given direct blood transfusions, slight oozing of blood continued even from the point in the first area, although the cutaneous incisions over the veins were sutured.

A surgical consultation was requested. Owing to the poor response of the patient to repeated blood transfusions and various forms of medical treatment, including snake venom and because of the past history, she was transferred to my service for a splenectomy after further study. An examination of the uterus and cervix revealed no gross pathologic condition. There was a constant general serosanguineous ooze from the uterus, but this was not coming from one definite area. The cervix was slightly inflamed and eroded owing to numerous repeated uterine packings. A dilatation and curettage was done for biopsy and the uterus was packed. The cervical os was touched up with silver nitrate. A pathologic report on the biopsy scrapings showed endometritis, this was not of an unusual character.

Under local anesthesia a biopsy specimen was taken from the sternal bone marrow. The pathologic report was as follows. The bone marrow was hyperplastic chiefly with normoblasts. Megakaryocytes were frequently seen.

Operation—The presence of megakaryocytes encouraged us to perform a splenectomy, and this was done on Sept 27, 1935 by one of us (A. X. U.) under general anesthesia. The operation was done rapidly and all bleeding points were promptly clamped and controlled, so that there was a minimal amount of bleeding and shock. The spleen was about twice normal size. Two splenuli were found and removed. The immediate postoperative condition was good.

The pathologic report was made by Dr. A. R. Casali. The spleen weighed 340 Gm, and was about twice normal size. The capsule was slate color, slightly thickened and wrinkled. The cut surface showed lymphoid hyperplasia and the pulp was red and soft. The two small accessory spleens present showed the same gross findings.

Microscopic examination showed that the lymphoid follicles were small (the gross examination was apparently erroneous), the sinuses were filled with mononuclears and red cells. Billroth's cords showed red cells, frequent normoblasts, lymphoid cells, a small number of polymorphonuclear leukocytes, occasional eosinophils, rare myeloblasts and reticular cell proliferation.

The diagnosis was hyperplastic spleen on the basis of thrombopenic purpura.

Spence⁵ has stated that most spleens removed are enlarged to twice normal size. Wiseman, Doan and Wilson⁶ have stated that the spleen is usually normal and never more than

5 Spence A. W. The Results of Splenectomy for Purpura Hemorrhagica. *Brit. J. Surg.* 15: 466, 1929.

6 Wiseman B. K., Doan C. A. and Wilson S. J. The Present Status of Thrombopenic Purpura. *J. A. M. A.* 115: 8 (July 6) 1940.

slightly increased in size, any case in which the spleen is easily palpated almost surely belongs to the symptomatic group of purpuras. Our case could not rightly belong to the symptomatic group even though the spleen was twice normal size. The mother and the first child, who was still-born, had severe purpura and after the splenectomy the mother has been free of all purpuric petechiae and hemorrhages, but the first living child had petechiae and a low platelet count. There was, presumably, evidence of a hereditary congenital defect.

Postoperative Course—The postoperative course was uneventful. When the patient was seen after she returned to her bed from the operating room there was no evidence of bleeding from the transfusion sites on the arms where there had been oozing previously from the cutaneous incisions, and there was no evidence of fresh bleeding from the uterus. This finding corresponds to the report of Brown and Elliott⁷ in which all evidence of hemorrhage ceased immediately after splenectomy in 2 of their cases. Two days after the operation the platelet count rose to 268,000 and steadily to 826,000 on the thirteenth day, after which there was a gradual fall, and on the day of her discharge from the hospital, twenty-five days after the operation, it was 124,000. Two years after she was operated on the platelet count was 75,000 and five years later it was 100,000. The bleeding time on the twelfth postoperative day was two minutes, on the eighteenth day one and one-half minutes, on the twentieth day one and one-half minutes, and five years later two and one-half minutes. There was a steady rise in the red blood cell count and in the hemoglobin content. The first postoperative day the red cell count was 3,980,000 and the hemoglobin 38 per cent. Eighteen days after the operation the red cell count was 5,040,000 and the hemoglobin 52 per cent. A blood examination made five years later showed red cells 4,600,000, leukocytes 13,100, hemoglobin 85 per cent, platelets 100,000, bleeding time two and one-half minutes, coagulation time four and one-half minutes, polymorphonuclear leukocytes 70 per cent, lymphocytes 26 per cent, eosinophils 1 per cent and monocytes 3 per cent. Although splenectomy results in clinical improvement it does not necessarily affect the platelet count except transiently. Two years and two months after the operation during the sixth month of pregnancy, the platelet count was 75,000. This finding corresponds to the findings reported by Evans,⁸ Brown and Elliott⁷ and Spence.⁹

Subsequent Pregnancies—One year and eight months after splenectomy she became pregnant. Her last period was on May 28, 1937. In the sixth month of her pregnancy her red blood cell count was 4,800,000 and the platelet count 75,000. Examinations of the urine during the antepartum period were negative. She felt well with no vomiting, no headache and no edema of the ankles. She was delivered in the hospital on March 12, 1938 of a full term living female child weighing 7 pounds 13 ounces (3,544 Gm.). It was a normal left occipito-anterior delivery and there was a normal amount of bleeding. On the day of delivery the blood showed 5,550,000 erythrocytes, 85 per cent hemoglobin, 60,800 platelets, bleeding time four and one-half minutes and coagulation time two minutes. The urinalysis was negative. She had a normal postpartum course.

Twenty-four hours after delivery the baby had petechiae on the face, buccal mucous membrane and soft palate. There were no free hemorrhages. The child was given a transfusion of 50 cc of blood. The next day there was evidence that the petechiae were beginning to fade and a few days later they disappeared. An examination of the baby's blood showed a bleeding time of five and one-half minutes and a platelet count of 23,200. On July 26, 1940 when this child was 2 years and 4 months old the blood showed a red cell count of 3,850,000, leukocytes 8,200, hemoglobin 79 per cent, bleeding time one and one-half minutes and coagulation time three minutes. Brown and Elliott⁷ also cited 1 case following splenectomy for thrombopenic purpura in which a woman gave birth to a child with all classic signs and symptoms of thrombopenic purpura.

Our patient again became pregnant and was delivered at home on Nov. 28, 1939 by one of us (C. I. H.) who had

delivered all her children. It was a breech delivery of a male child. There was a normal antepartum course with negative urinalysis, normal blood pressure readings and no purpuric manifestations. The child was normal, full term and free of any petechiae. Five minutes after the placenta was delivered the mother suddenly became cyanotic and clammy, with a complaint of sudden severe pain in the chest accompanied by dyspnea. This episode suggested pulmonary embolism. Her condition improved and she made a good recovery. She has felt well since. Her blood picture has been satisfactory and she has had no complaints and has been symptom free of her previous condition.

A blood examination done on the second child on July 26, 1940 showed erythrocytes 4,950,000, leukocytes 14,600, hemoglobin 80 per cent, polymorphonuclear leukocytes 45 per cent, lymphocytes 50 per cent, mononuclears 4 per cent, basophils 1 per cent, bleeding time one minute and coagulation time two minutes. No record of the platelet count can be found.

She again became pregnant in 1941. Her last menstrual period was Dec. 20, 1940. Her antepartum course was completely uneventful. On Oct. 14, 1941 she was delivered of a living full term male child by breech presentation. The labor was extremely short—about two and one-half hours. About five minutes after the placenta was delivered she complained of a sudden severe pain in the chest and difficulty in breathing and cyanosis became intense. She recovered from this episode in a short time and remained perfectly well during the remainder of her postpartum period. Further check-up on the mother and children at this time was impossible since the family moved to another city.

The patient has been followed for seven years and she has shown no tendency to have hemorrhages, purpura or weakness; she stated that her menses have been normal with no excessive bleeding, and that she has felt well since the operation. At present she is said to be employed in a factory.

SUMMARY

The case of thrombopenic purpura here reported was followed for eleven years before operation and for seven years after splenectomy. The following are the salient facts of the case:

1. She had several admissions to the hospital for hemorrhages.
2. Before being operated on she was delivered of a full term stillborn male fetus. The fetus had a purpura similar to the mother's. Nineteen days post partum the mother was readmitted to the hospital for treatment of severe bleeding from the uterus.
3. After repeated blood transfusions and extensive medical treatment without cessation of hemorrhage a splenectomy was performed and resulted in apparent clinical cure.
4. Two years and six months after the splenectomy she gave birth to a full term living female child weighing 7 pounds 13 ounces. The mother had a normal antepartum and postpartum course without any signs or symptoms of purpura. Twenty-four hours after delivery the child had a petechial purpura which disappeared in a few days. Examination of the blood of this child revealed anemia, bleeding time prolonged to a degree and a decided decrease in the platelet count from normal.
5. Four years after splenectomy the patient gave birth to a living full term male child.
6. Six years after splenectomy she gave birth to a full term living male child, making a total of three living children after operation.
7. The last two children born were apparently free from any blood dyscrasia.
8. In the last two pregnancies the mother had a normal antepartum course and was free from any purpura, but immediately after the placenta was delivered in each instance she had a sudden attack simulating pulmonary embolism, from which she made an uneventful recovery in a short time. These attacks may be related to her history of thrombopenic purpura.
9. At the time of writing the patient feels well and has returned to her employment in industry.

STUDIES ON THE MECHANISM OF ARTERIAL HYPERTENSION

CLINICAL LECTURE AT ATLANTIC CITY SESSION

IRVINE H. PAGE, M.D.

INDIANAPOLIS

It seems profitable from time to time to stop during the course of an investigation and look back rather than forward to determine how well the body of knowledge is being built. In the past years the quest to understand the mechanism of hypertension has occupied many investigators, but by force of circumstances at this time I must limit my remarks to the work which has especially concerned us in the Lilly Clinic. My associates have presented more comprehensive reviews elsewhere which, we hope, exhibit the relationship of our work to that of the many others who are contributing to this vast field so fruitfully.

I should begin this running account somewhere about 1930, since at that time very few investigators were studying hypertension. Our work was largely concerned with two approaches to the problem, namely a search for a pressor agent which could cause hypertension in man¹ and an attempt to ascertain the part played by the nervous system in the genesis of hypertension². Since no thoroughly reliable method was at hand for the production of hypertension in animals, the investigations were almost wholly limited to man.

It may be recalled that the general position of the problem at that time was that hypertension was due to overactivity of the nervous system, that attempts to lower blood pressure were considered dangerous, owing to development of renal insufficiency, and that essential hypertension was characterized by normal renal function.

As regards the first of these propositions, extensive work by various surgeons in collaboration with internists has left little doubt that in man, at least, most cases of hypertension are not directly caused by hyperactivity of the nervous system. But this led to an unhealthy reaction. The nervous system was promptly relegated by some to complete oblivion. It is becoming more and more evident that the nervous system both contributes to hypertension by directly causing vasoconstriction, especially when rapid adjustment of pressure is required, and aids in the maintenance of the body in a state such that it is capable of responding to humoral stimuli which elevate pressure³.

The second of these beliefs, namely that elevated blood pressure must not be lowered lest the kidneys fail in their function, has been an especially difficult view to combat, and this goes back as far as Cohnheim. It seems firmly fixed in some clinical teaching that hypertension occurs for a purpose, that it is a compensatory phenomenon. We became convinced that this

was not true very early in our studies⁴ because we found that blood pressure could be lowered in hypertensive patients by a variety of means and that not the slightest evidence of insufficient tissue perfusion occurred, nor was there any change in overall renal efficiency as measured by urea clearance or ability to concentrate urine. Subsequent to this work it has been shown time and time again that this is true, yet the notion of the compensatory nature of hypertension still persists.

The last of these beliefs, that renal function was normal in hypertension, has also been disproved. The important concept of "clearance," which originated with Van Slyke, has been elaborated and implemented by the brilliant studies of Smith and his associates. Application of this tool to hypertension has been made in Smith's laboratory, particularly by Goldring and Chasis, and in our own by Corcoran. In short, it has become abundantly clear that, while the excretory function of the kidneys may not be impaired early in the course of the disease, intrarenal hemodynamic changes of great importance occur. It is no longer sufficient in the study of hypertension to limit the examination to the excretory powers of the kidneys. It is a growing con-

Fig 1—The effect of increasing amounts of angiotonin injected intravenously into a cat with the central nervous system destroyed. The upper graph represents arterial blood pressure the second respiration the third the base line the fourth the time in intervals of one minute and the fifth the time of injection. The first injection represents 0.01 cc and the last 0.1 cc with increases of 0.01 cc in the interval.

viction that the diversity of action of the kidneys has been greatly underrated.

With these thoughts generally prevailing, it was to be expected that the so-called surgical treatment of hypertension should have been actively pursued, especially by the now famous teams of Allen, Adson and Brown, Peet and his associates and Smithwick. And Dr. George Heuer and I also made such studies. We came to the conclusion several years ago, and have not changed our belief since, that this treatment is palliative and not curative, that in many patients a period of from two to seven years of respite from the severely damaging effects of hypertension could be secured and that this was desirable if the operation itself were not too drastic.

The search for a pressor substance in hypertensive patients was conditioned by the thinking of the day, namely that nervous impulses were transmitted by chemical substances of very simple structure, such as acetylcholine, and that all known pressor and depressor substances were also of relatively simple structure and the pressor agents mostly limited to the group of

phenolic amines Having been in Germany in Volhard's clinic, I had seen some of the early work on renin but was unimpressed, as most of the men in that clinic were. The fact was we did not see the relationship between the kidneys and hypertension.

Extended studies with methods which we believed should have shown the presence of excess amounts of

Fig. 2—A branching arteriole and venule in a moat chamber in a rabbit's ear showing the normal diameter of the vessels. Figures 2, 3, 4 and 5 show the effect of the injection of angiotonin and induction of renal hypertension on the vessels of the rabbit's ear from work of Abell and Page.

phenolic amines in the blood and urine of hypertensives failed to show their presence in excess.⁶ Since this work had left us convinced that this approach to the humoral mechanism of human hypertension was unprofitable, work on the pressor agent discovered by Tigerstedt and Bergman in the kidneys was started. Repetition of their work and that of Bingel and Strauss⁷ and of Hessel⁸ left no doubt that a pressor substance was present but that it was not a simple amine. It was associated with a protein fraction.

At this time Goldblatt's contribution appeared and naturally we were in haste to reproduce it. We did so and there was not a doubt in our minds that he had taken a step forward of the greatest importance.

It seemed necessary at this time to study more carefully the relationship of the nervous system to hypertension in animals with experimental hypertension to make perfectly certain that it was not the core of the problem of hypertension. To have made a mistake in choosing the road to travel would have been a catastrophe—at least a minor one. A number of investigators realized this and performed yeoman service. The task of systematically removing various portions

of the nervous system to show that these operations were mostly without important effect, at least in dogs, was a thankless but important one. This is an extremely interesting story but would lead us too far afield at the moment to go into it more deeply. Despite the seeming unimportance of these studies and the little attention they have received, it is my belief that a much more thoughtful reevaluation of the importance of the nervous system in its relation to hypertension is soon to occur. At any rate, these studies served to clear the deck and forced attention on the possibility of the participation of a humoral mechanism in hypertension.

Some of us felt that extensive studies on the physiology of pressor kidney extracts, that is, renin, would be unsatisfactory because of their crudeness, being as they were mixtures of pressor and depressor agents. Helmer and I⁹ therefore attempted to purify these extracts and obtain a product with reasonably constant chemical and physiologic properties. During the various steps in the purification the fractions were tested in both intact animals and perfused rabbits' ears. The latter preparation was used because at that time our conviction was very strong—too strong—that the pressor agent of hypertension must act almost exclusively directly on the peripheral vessels. The interesting fact emerged from these tests that, as the renin became

Fig. 3—The same vessels at the time of greatest arterial constriction following injection of 0.2 cc. of angiotonin.

more active in intact animals, it caused less vasoconstriction in the perfused ear. Finally a preparation was made which was highly pressor in cats but caused no vasoconstriction in the ear. It was also obvious that, as purification proceeded, something had been removed which was necessary for the pressor action of renin. This something proved to be contained in the pseudoglobulin fraction of blood, as Kohlstedt, Helmer

⁶ Page I. H. Vasopressor Action of Extracts of Plasma of Normal Dogs and Dogs with Experimentally Produced Hypertension, *Proc. Soc. Exper. Biol. & Med.* 35: 112, 1936. Pressor Substances from the Body Fluids of Man in Health and Disease.¹

and I¹⁰ showed, and was named renin activator. It was stated at that time and is reiterated here that the term "renin activator" connotes merely that renin is inactive in the absence of this special protein contained in blood. Nothing was implied as to the nature of the action between the two substances. Much evidence indeed suggests that renin is an enzyme and acts on a

Fig 4—The same vessels after the arteriole had returned to its normal diameter

substrate, i. e. renin activator. It was quite clear to our group after these observations and also to the able group of investigators working with Houssay and Braun-Menendez that the pressor substance was not renin itself but a third substance formed as the result of interaction of renin and renin activator. This proved to be true, and both groups showed that this third substance was a heat stable, dialysable material with strong pressor properties (fig 1). Helmer and I named the substance "angiotonin," a somewhat nonspecific term calculated to avoid implications of function.¹¹ The name "hypertensine," given by the South Americans, seems to us attractive but decidedly premature in its implications.¹² The task ahead—not behind—is to show whether or not angiotonin is in truth the chemical agent mediating hypertension.

EVIDENCE

Having separated angiotonin, we were in a position to see whether it had properties consonant with those required of a substance which could cause essential hypertension in man or renal experimental hypertension in animals. Let us now turn to an examination of this evidence.

¹⁰ Kohlstaedt K. G., Helmer O. M. and Page I. H. Activation of Renin by Blood Colloids. *Proc. Soc. Exper. Biol. & Med.* 39: 214, 1933.

¹² Braun-Menendez E., Fasciolo J. C., Leloir L. F. and Muñoz J. M. The Substance Causing Renal Hypertension. *J. Physiol.* 98: 283 (July) 1940.

1 *An Especial Type of Peripheral Vasoconstriction*—Since patients with hypertension do not have cold, pale skins, it is evident that the arteriolar constriction which is the chief cause of the pronounced increase in peripheral resistance is of an especial sort. Such a balance must be struck between the pumping force of the heart and the degree of narrowing of the peripheral arterioles that the arterial pressure rises but flow of blood to the tissues is not reduced. Such pressor agents as epinephrine and pitressin obviously could not be concerned in the genesis of this kind of hypertension because of the severe reduction of peripheral flow they cause. Angiotonin appears unusual among pressor substance in its ability to produce just the kind of vasoconstriction which occurs in essential hypertension. This can be shown not only by measuring the skin temperature after injection of angiotonin but by direct observation of the vessels which have grown into a quartz chamber in the ear of a rabbit¹³ (figs 2, 3, 4 and 5).

It is interesting that the constriction of the vessels in the ear of a rabbit in which angiotonin has been injected are indistinguishable from those in rabbits in which experimental renal hypertension has been induced¹⁴ (fig 6). This constitutes evidence of importance that there is real similarity between the action of the humoral agent of hypertension and angiotonin.

Fig 5—The same vessels after the rabbit has become hypertensive. The arterial pressure is 15 normal. The arteriole is constricted to approximately the same degree as that which occurred following injection of the angiotonin.

2 *Changes of Intrarenal Circulation*—It has been too long supposed, largely on the basis of technically inadequate methods, that "renal function," i. e. excretory function, is entirely normal, at least in early hypertension. Actually it has been shown that there occurs

¹³ Abell R. G. and Page I. H. The Reaction of Peripheral Blood Vessels to Angiotonin, Renin and Other Pressor Agents, *J. Exper. Med.* 75: 305, 1942.

¹⁴ Abell R. G. and Page I. H. The Effects of Renal Hypertension on Vessels of the Ears of Rabbits. *J. Exper. Med.* 75: 673 (June) 1942.

a characteristic change in the flow of blood through excretory renal tissue¹⁵. Even the simple methods of estimation of renal function indicate that the ability of hypertensive patients to concentrate urine is early impaired well before lowering of urea clearance has indicated loss of function¹⁶.

The characteristic circulatory change consists of a tendency to decreased renal blood flow and a consistent increase of the head of pressure within the glomerular capillaries. If without changing arterial pressure, for example, the small arteriole distal to the glomerulus, the so-called efferent arteriole, had constricted increased intraglomerular pressure and decreased blood flow would inevitably result. Actually it appears from a recent mathematical analysis (Lampert) of renal hemodynamics in this disease that there has occurred constriction of both the afferent and the efferent arterioles. The increase in resistance of the afferent arteriole seems to protect the fragile glomerular capillaries from the increased systemic pressure, catching it out so that the back pressure of the constricted efferent arterioles is probably the origin of the increased

nearly all the diodrast in the renal blood is excreted in a single passage (Corcoran, Smith and Page). Therefore, if 5 mg of diodrast (as iodine) appears in one minute's urine and there is 10 mg per hundred cubic centimeters of plasma, it follows that very nearly 500 cc of plasma has perfused in contact with excretory cells in that minute. Under such conditions, then, plasma diodrast clearance is 500 cc and is equal to the plasma flow to functionally active renal tissue. Knowing the hematocrit ratio, renal blood flow may then be calculated. The error of the calculation is probably not greater than 10 per cent. Inulin, on the other hand, is an inert polysaccharide excreted only because of the fact that it exists in solution in the plasma water. As glomerular filtrate is formed by the filtration pressure present in the glomerular capillaries inulin passes out with water and salt and dextrose and urea. Unlike all of these none of it is reabsorbed. The amount which appears in the urine is the amount present in the glomerular filtrate. Thus if 100 mg occurs in one minute's urine and there is 100 mg in 100 cc of plasma, it may be concluded that 100 cc of water was filtered from the plasma in that minute. Therefore, knowing the simultaneous plasma clearances of diodrast and inulin we know within narrow limits the volume of plasma (or whole blood) which perfuses the kidneys and the volume of water expressed from that plasma during glomerular filtration. It will be admitted that such observations are neither in themselves empirical nor inexpressive of functional change. The validity of the interpretation of such data in terms of individual arteriolar resistance is perhaps more subject to challenge since this demands further measurements (blood pressure, plasma protein content) themselves subject to error.

Returning now to hypertensive patients it is found that filtration rate (inulin clearance) is well maintained, while there is in many—but by no means all—a tendency to reduced renal blood flow. Maintenance of filtration at normal levels while plasma flow is somewhat reduced indicates that there has occurred an increased pressure head in the glomerular capillaries so that more water is squeezed from less blood. Since in spite of increased systemic pressure renal blood flow is often less than normal it is apparent that there must have occurred increased renal resistance. This increased resistance is due to constriction distributed between the afferent and efferent arterioles.

Since such constriction is characteristic of hypertension it would be reasonable to insist that angiotonin reproduces this change before accepting it as being concerned in the genesis of the disease. Actually, we have found in dogs and man¹⁷ that it does this with great facility. Similarly, the occurrence of normal rates of renal perfusion in some human hypertensive patients would challenge any parallelism of human hypertension with experimental renal disease if it is assumed that the experimental disease is due to renal ischemia in the sense of a deficit in total perfusion with blood. However as we have pointed out¹⁸ blood flow through the kidneys in hypertension clinical or experimental seems to depend on a balance struck between increased resistance and increased pressure. Neither the presence of

HD/Tm, cc/min	234	170	205
RA mm. Hg/cc	0.89	57	32
RE mm. Hg/cc	0.81	17	111
R mm. Hg/cc	1.70	74	431
Pressure mm. Hg/cc	100	184	143

Fig. 6—Schematic representation of renal status in untreated and treated (renal extract) hypertensive patients as compared with the normal. The values HD/Tm refer to renal blood flow per unit of tubular mass (Tm) and RA, RE and R respectively to calculated (Lampert 1942) resistance through afferent and efferent arterioles and total arteriolar resistance in millimeters of mercury per cubic centimeter of blood per minute. The pressure is the mean of brachial systolic and diastolic pressures. The data and conclusions were presented by Corcoran and Page. Fed Proc 1 17 1942.

intraglomerular pressure. Because of the increased systemic pressure the rate of blood flow through excretory tissue is frequently within the normal range in spite of arteriolar constriction and, presumably, sclerosis.

The basis for these conclusions as to the nature of renal circulation in hypertension is determination of the plasma clearances of diodrast and inulin. Conclusions drawn from these and similar methods of observation have been loosely criticized as inaccurate and inconclusive in part because by analogy and recollection they are thought of as empirical tests of kidney function¹⁹ rather than observations based on sound evidence. Because of this misconception a few lines may be devoted to them.

Briefly, diodrast is excreted by the secretory activity of the tubular cells. This activity is so intense that, when the blood diodrast concentration is not too high

ischemia nor its absence is of itself evidence for or against the renal genesis of hypertension. Renal ischemia may develop in some cases and not in others. The same is true in dogs in which the stimulus to the production of hypertension is renal, i.e., a clamp on the renal artery or silk perinephritis.

3 Cardiodynamic Effects—I said before that the force of the heart beat must be augmented in order that arterial pressure may rise and yet reduction in peripheral blood flow not occur. Clinically this augmented force is easily recognized by the heave and thrust of the heart and its ultimate hypertrophy. The heart is a specialized portion of the vascular system, therefore it is not surprising that substances which act on the peripheral vessels will act on it as well.

Angiotonin has very profound cardiodynamic effects. I shall not describe the beautiful experiments of Wilkins and Duncan,¹⁹ Bradley and Parker,²⁰ Lorber²¹ and Hill and Andrus,²² but content myself with the observation that both the force of the beat and the efficiency of the muscle of the heart are increased by angiotonin. On the other hand, some evidence is found that at least during the acute effects of the drug during brief experiments, certain signs of cardiac failure appear. This may be due to failure of adaptation to occur in short lived experiments.

Taylor and I²³ used the ballistocardiograph, which Starr, Hamilton and Cournand have investigated so intensively, to record some of the activities of the heart when angiotonin was injected. We were immediately impressed by the similarity of the tracing of the hypertensive with that of the normotensive made hypertensive by injection of angiotonin, and how dissimilar were the tracings following injection of tyramine and methylguanidine. The last two pressor agents were used because in the rabbits' ears they produced vasoconstriction resembling that of angiotonin more closely than the other drugs studied (fig 7).

Cardiac output is definitely reduced by angiotonin as a result both of reduction in stroke volume and of pulse rate as well. Many hypertensive patients also have reduced cardiac output. In many others this reduction is probably compensated for by enlargement of the heart.

Of especial interest is the fact that angiotonin elevates blood pressure almost asymptotically, while other known pressor agents produce severe symptoms and signs.

This evidence, combined with that of other investigations, demonstrates pronounced similarity in the cardiodynamic effect of angiotonin and the cardiodynamics of naturally occurring hypertension. The similarity is not complete at the present stage of knowledge, and more information on this vascular segment is to be desired.

4 Presence of a Vasoconstrictor Substance in the Renal Vein Blood and Peripheral Blood—When hypertension is induced by reducing the pulse pressure by

a clamp on either the renal artery or the scar following perinephritis in dogs, it can be shown that a vasoconstrictor agent appears in the blood of the renal vein and in the peripheral blood as well.²⁴ This is true also of the peripheral blood. Whether this is angiotonin or not is still uncertain. We have made an extensive study of it and I believe at present that the evidence is in favor of its being angiotonin combined with a protein carrier. Since it appears in the blood in both experimental and naturally occurring hypertension and following the injection of renin, this is suggestive evidence in favor of its being angiotonin-like.

There are many other similarities between angiotonin and the naturally occurring humoral agent of hypertension, but this must suffice for the present. Study of these similarities is, I believe and hope leading to an understanding of the mechanism of hypertension itself. And inherent in such studies is the gradual evolution of methods adapted to the clinical analysis of hypertensive patients. While many of them must still be employed in research clinics it would not be over-

Fig 7—Ballistocardiographic tracing of normal persons after injection of tyramine, methylguanidine sulfate and angiotonin. The last pair of tracings are of a hypertensive patient before and after treatment with kidney extract.

confident to predict that, in the not distant future, they will be sufficiently simplified for more general bedside use.

KIDNEY EXTRACTS

I will not detail the reasons why we believed that extracts of kidneys contain a substance or, more probably, substances which destroy angiotonin, which reduce arterial pressure and which cause reversal of the vascular lesions in the eyegrounds of patients exhibiting the malignant syndrome. Suffice it to say that there are good physiologic reasons. But the preparation and assay of these extracts are matters of great difficulty. Since nothing is known of the chemical properties of the substance sought, the preparation of active extracts is almost purely a hit or miss problem.

What may be expected of relatively crude extracts of kidney when injected into hypertensive dogs, rats or human beings? A slow, progressive fall in arterial pressure occurs in many but not all of the subjects. During the first few days of the injections—which are given daily—a little fever may occur, but it then disappears. The fall in blood pressure is seldom to normal.

in human beings, often to far below normal in animals, and the diastolic pressure usually is reduced comparatively more than is the systolic. After several weeks of treatment it may be noticed both by patient and by physician that regressive changes in the retinopathy are occurring and several months later hemorrhages, exudates and papilledema may all have disappeared.

From time to time moderate to severe reactions to the material have occurred. These usually consist of a sudden fall in blood pressure several minutes after the extract has been administered along with cramping pains in the back or chest. These reactions often are very unpleasant, but no serious complications have resulted from them.

The mechanism of the action of these extracts must be very complicated. At present we are working on the hypothesis that their action is chiefly due to their ability to destroy angiotonin, in short, that they contain enzymes, angiotonases, which destroy angiotonin. Up to the present there is no proof that this is so, nevertheless, it is an attractive hypothesis. There is some evidence in favor of this view, briefly as follows.

Angiotonin Destruction and Angiotonases—It angiotonin and kidney extract are mixed, incubated thirty minutes and boiled, and the filtrate is tested for pressor activity on a pithed cat, angiotonases could be estimated.²⁵ Indeed, there appear to be at least two of them, the optimum activity of one being at about pH 4.0 and of the other at about pH 7.5.

The next step, namely the demonstration that angiotonase activity and antipressor activity go hand in hand, has not as yet been taken. Of one thing we feel sure, and that is that the enzyme with a pH optimum of 4.0 does not reduce blood pressure in human beings with hypertension. It is quite evident that a matter of importance is involved in the question of the identity of angiotonase and antipressor activity, hence the evidence must be very convincing before it is acceptable.

Action of Kidney Extract on Renal Hemodynamics—If we assume that there is a relationship between the action of kidney extracts and their angiotonase content, the results obtained from a study of their action on human and dog kidneys is understandable. Corcoran and I²⁶ found a decrease in glomerular efferent arteriolar tone in most patients treated with kidney extract, and an associated increase of functionally effective renal blood flow. This is just the reverse of the renal action of angiotonin itself, as I have already explained. No evidence was obtained that regeneration of tubular cells occurred, but further progressive loss of tubular tissue was not usual. Thus renal extracts seem to decrease the angiotonin-like intrarenal vasoconstriction and, probably because of the decrease of arterial pressure, attenuate the progress of renal tissue destruction. Even these results cannot be accepted as unequivocal evidence in favor of our working hypothesis because of the possibility that these actions might be complicated by the presence of very small amounts of pyrogens. It has been shown by Chasis, Ranges, Goldring and Smith²⁷ that pyrogens cause acute increases of renal blood flow, largely because of efferent vasodilatation. While our measurements were made only in subjects who were

fever free for the previous twenty-four hours, nevertheless the action of pyrogens might be more subtle than is at present suspected.

Effect of Kidney Extract on Cardiac Output—Cardiac output is usually either normal or decreased in hypertension. The reduction in stroke volume is easily seen on the ballistocardiographic tracing and, as Starr pointed out, the contour of the curve of hypertensive patients may be similar. It closely resembles the curve obtained when angiotonin is injected into normotensive human beings. For these reasons it seemed of interest to Taylor and me to see if kidney extract altered some of these phenomena toward normal.

In brief, it was found that in 15 patients in whom the blood pressure was reduced from an average mean of 174 mm of mercury to 140, cardiac output as measured by the ballistocardiograph was increased roughly 15 to 20 per cent. When extract was discontinued and arterial pressure rose, the cardiac output decreased to its former level.

The contour of the ballistocardiographic tracing often seen in hypertensive patients was lost and replaced by the contour seen in normotensive persons when the arterial pressure fell as a result of injecting kidney extract.

The Outlook for Kidney Extracts as Therapeutic Agents—It now seems reasonably established that kidney extracts contain substances with physiologic effects some of which seem desirable from the therapeutic point of view. But these substances have not been separated and nothing is known of their chemical nature or of the way in which they produce their effects.

It is particularly important at this stage of the investigation not to confuse the issue by the use of loose expressions such as "specific" and "nonspecific." We do not know and will not know, until the various active principles are separated, to what substance or substances can be attributed the multiple action of these extracts.

It has long been realized that fever is often associated with fall in arterial pressure, and this would be expected on the basis of what is known of the hemodynamic changes which occur. It is not known, however, whether a rise in body temperature is a necessary part of this phenomenon. Furthermore, almost nothing is known about the manner of action of pyrogens.

The use of pyrogens has been advocated from time to time in the treatment of hypertension. Several years ago we employed injections of colloidal sulfur, protein and heavy metals. We gave it up because of the lack of conviction the results carried. Lately we have used typhoid vaccine on 2 patients with advanced renal failure with the result that severe hematuria occurred in both. A disastrous fall in renal function occurred in 1 and a less serious fall in the other. From this experience we believe that this particular pyrogen must be employed with the greatest care, if at all when renal insufficiency is present.

The yields of the active materials in kidney extract are very poor, and a great deal has yet to be learned about stability and similar practical issues. Substances which sensitize the body have not been completely eliminated, hence this danger has always to be considered.

For these reasons I am forced to view the work on kidney extract as an experiment of great interest, but one which must be much further pursued before one has the right to suggest it as a treatment in the true sense of the word.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Acting Secretary

DEXTROSE (See New and Nonofficial Remedies, 1942, p. 418)

The following dosage forms have been accepted

THE UPJOHN COMPANY, KALAMAZOO, MICH

Dextrose 5% W/V in Distilled Water 500 cc and 1,000 cc Upjohn Infusion Bottles Each hundred cubic centimeters contains dextrose, 5 Gm

Dextrose 10% W/V in Distilled Water 500 cc and 1,000 cc Upjohn Infusion Bottles Each hundred cubic centimeters contains dextrose, 10 Gm

Dextrose 20% W/V in Distilled Water 500 cc and 1,000 cc Upjohn Infusion Bottles Each hundred cubic centimeters contains dextrose, 20 Gm

Dextrose 5% W/V in Physiological Solution 500 cc and 1,000 cc Upjohn Infusion Bottles Each hundred cubic centimeters contains 5 Gm of dextrose and 0.85 Gm of sodium chloride-U S P

Dextrose 10% W/V in Physiological Solution 500 cc and 1,000 cc Upjohn Infusion Bottles Each hundred cubic centimeters contains 10 Gm of dextrose and 0.85 Gm of sodium chloride-U S P

Dextrose 5% W/V in Ringer's Solution 500 cc and 1,000 cc Upjohn Infusion Bottles Each hundred cubic centimeters contains 5 Gm of dextrose, 0.7 Gm of sodium chloride-U S P, 0.03 Gm of potassium chloride-N F and 0.025 Gm of calcium chloride-U S P

Dextrose 10% W/V in Ringer's Solution 500 cc and 1,000 cc Upjohn Infusion Bottles Each hundred cubic centimeters contains 10 Gm of dextrose, 0.7 Gm of sodium chloride-U S P, 0.03 Gm of potassium chloride-N F and 0.025 Gm of calcium chloride-U S P

PHENOBARBITAL SODIUM (See New and Nonofficial Remedies, 1942, p. 470)

The following dosage forms have been accepted

THE LAKESIDE LABORATORIES, INC., MILWAUKEE

Ampuls Solution Phenobarbital Sodium and Benzyl Alcohol 1 cc and 2 cc Each cubic centimeter contains 0.162 Gm (2½ grains) of phenobarbital sodium and 0.02 Gm of benzyl alcohol dissolved in propylene glycol

PENTOBARBITAL SODIUM (See New and Nonofficial Remedies, 1942, p. 462)

The following dosage forms have been accepted

THE LAKESIDE LABORATORIES, INC., MILWAUKEE

Ampuls Solution Pentobarbital Sodium and Benzyl Alcohol 1 cc and 2 cc Each cubic centimeter contains 0.162 Gm (2½ grains) of pentobarbital sodium and 0.02 Gm of benzyl alcohol dissolved in propylene glycol

LYOVAC NORMAL HUMAN PLASMA (See New and Nonofficial Remedies, 1942, p. 482)

SHARP & DOHNE, INC., PHILADELPHIA

Vacule Ampul-Vial Lyovac Normal Human Plasma Containing an amount (preserved with phenyl mercuric nitrate 1:25,000) to yield 50 cc of restored plasma, packaged with a 50 cc bottle of distilled water as a diluent (preserved with phenyl mercuric nitrate 1:100,000)

ISOTONIC SOLUTION OF SODIUM CHLORIDE (See New and Nonofficial Remedies, 1942, p. 425)

The following dosage form has been accepted

THE UPJOHN COMPANY, KALAMAZOO, MICH

Physiological Solution of Sodium Chloride 500 cc and 1,000 cc Upjohn Infusion Bottles Each hundred cubic centimeters contains 0.85 Gm of sodium chloride-U S P in distilled water

Council on Foods and Nutrition

RECENT RESTRICTIONS ON THE SALE OF SUGAR IN THE UNITED STATES HAVE FOCUSED ATTENTION ON SOME OF THE NUTRITIONAL PROBLEMS ASSOCIATED WITH THIS COMMODITY. SOME RESTRICTION OF THE CONSUMPTION OF SUGAR MAY BE DESIRABLE FROM THE STANDPOINT OF PUBLIC HEALTH. THE CONSUMPTION OF SUGAR AND OF OTHER RELATIVELY PURE CARBOHYDRATES HAS BECOME SO GREAT DURING RECENT YEARS THAT IT PRESENTS A SERIOUS OBSTACLE TO THE IMPROVED NUTRITION OF THE GENERAL PUBLIC. THE COUNCIL DECIDED TO SUMMARIZE ITS VIEWS ON THIS SUBJECT AND HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

FRANKLIN C. BING, Secretary

SOME NUTRITIONAL ASPECTS OF SUGAR, CANDY AND SWEETENED CARBONATED BEVERAGES

Sugar, like flour, is a highly processed food which is considered to be a staple item in the modern diet. The Council in 1939 authorized the publication by Cowgill¹ of a report entitled "The Need for the Addition of Vitamin B₁ to Staple American Foods." On the basis of the material reviewed in that report, the Council² adopted certain policies relative to restoration to processed foods of nutritive values lost in preparation. These policies later formed the basis for recommendations by the Food and Nutrition Board of the National Research Council, which in turn led to action taken jointly by the cereal industry and the government to make available and to promote the preferential use of the white flour and white bread which now are designated "enriched."

Accompanying tabulations (tables 1 and 2) contain comparative estimates of the thiamine provided by sample diets selected from the literature. These and other data indicate that modern diets have provided only from a third to a half of the amount of thiamine contained in earlier diets.

The report of Cowgill brought out certain facts which bear importantly on the subject of the present report on the significance of sugar in nutritional economy. Whereas cereal grains consumed in the form of undermilled flour, rich in thiamine, formerly contributed as much as 50 or 55 per cent of the calories of the average diet, the contribution of flour to the average diet of recent times has been only about 25 per cent. The place represented by the difference between the 50 or 55 per cent of all calories formerly contributed by flour, and the 25 per cent later contributed, has been taken by other foods and mainly by sugar.

LARGE CONTRIBUTION OF CALORIES AS SUGAR

The per capita annual gross consumption of sugar in the United States increased steadily from about 10 pounds (4.5 Kg) in 1821 to 108 pounds (49 Kg) in 1931. Since then this gross consumption has shown little change. The latest available and more accurate estimate, which corrects for industrial non-food uses of sugar, and that exported as part of processed fruit, condensed milk and other foods, places the present annual per capita consumption at about 85 pounds (38.6 Kg). Even this amount represents 420 calories daily, or from 13 to 17 per cent of the 2,500 to 3,000 calories of an adult average diet.

Sugar as consumed in recent years, whether it originates from sugar cane or sugar beets, is for the most part highly refined sucrose. What vitamins or minerals may have been present in the cane or in the beets are almost completely removed in the processing of crystalline sugar. The finished product is practically chemically pure sucrose. Consumption of molasses, other syrups and brown sugar, compared to that of white sugar, is relatively small. Some inorganic salts can be found in them, but because of the nature of their preparation their content of thiamine is disappointing. Furthermore, not included in reports of the consumption of sugar are considerable amounts of corn starch and corn sugar (dextrose). These products are highly purified and as free from vitamins and minerals as crystalline sucrose.

1 Cowgill, G. R. The Need for the Addition of Vitamin B₁ to Staple American Foods. J. A. M. A. 113: 2146 (Dec. 9) 1939.

2 Council on Foods and Nutrition, Annual Meeting. J. A. M. A. 113: 680 (Aug. 19) 1939.

These circumstances reveal that the increased use of sugar since the middle of the nineteenth century has carried responsibility of almost the same order of magnitude as the roller milling of wheat for the very great lowering of the thiamine content of the average diet. There also undoubtedly has occurred a comparable loss of nicotinic acid (niacin) in diets, although this is more difficult to estimate. Other foods than the cereal grains either contain little thiamine or are not consumed in large enough amount to contribute importantly to the daily dietary allowances of thiamine, therefore, if the average diet is to be made to provide allowances of thiamine (and niacin?) comparable to those provided by former diets, a point of attack almost as important as roller milled white flour is sugar.

INTERFERENCE WITH A SATISFACTORY SUPPLY OF THIAMINE AND OTHER VITAMINS

What could or should be done about sugar? It is technically possible to augment certain of the nutritive qualities of sugar as was done with flour, by making restorative additions of desired nutrients. Or the aim could be at assuring a lower per capita consumption of sugar so that the contribution of sugar calories, which carry insignificant amounts of vitamins and minerals, would be curtailed to what it was before sugar became abundantly available. Before exploring either of these possibilities, other reasons for concern about the recent level of consumption of sugar may be considered.

Biochemical investigation has revealed that the oxidative activities of tissue cells, whereby energy is released from foods, depend on the presence in the cells of respiratory enzyme systems. It also has been shown that the vitamins thiamine, niacin and riboflavin represent indispensable constituents of the major enzyme systems concerned with oxidation of carbohydrate (dextrose). When deficiency exists in the supply of thiamine the oxidation of sugar is impeded to such a degree that products of its incomplete oxidation can readily be demonstrated in the blood. If the tissues possess ample reserves of vitamins no harm is done by ingesting carbohydrate but since sugar makes no contribution to such reserves the vitamins required must come from other foods. It follows that when the vitamin poor constituents of a diet sufficiently outweigh the vitamin providing constituents, a situation is created from which deficiency disease will logically result. Such a situation can readily develop

TABLE 1—Analysis of English Diets for Adult Men*

	Calories	Protein Gm	Cal Gm	Iron Mgs	Vitamin A Units	Ascorbic Acid Mgs	Total Fat Mgs

* From J. C. Drummond's *The Englishman's Food* (London: Cape, 1940).

† A diet containing as little thiamine as this (0.2 mg. per thousand calories) provokes symptoms of severe beriberi. See Williams, Mason, Smith and Wilder.³

‡ For moderate activity.

Experiments were performed by Williams and his associates⁴ with diets constructed to simulate the hypothetical average American diet. That is to say, the calories from unenriched white flour contributed 30 per cent of all the calories and those from sugar and other vitamin free foods 10 and 5 per cent, respectively. These diets, fed for several months, provoked the symptoms and chemical disturbances of beriberi.

³ Williams R. D., Mason H. L., Smith B. F. and Wilder R. M. Induced Thiamine (Vitamin B₁) Deficiency and the Thiamine Requirement of Man. Further Observations. *Arch. Int. Med.* 69: 721 (May) 1942.

The "average" American diet thus appears to be inadequate except when its foods, other than its content of flour and sugar are very wisely chosen. The situation is one in which the necessity for discriminating selection of foods is greater than can be viewed with equanimity. Unless all flour and all bakers' bread becomes enriched, provision of thiamine and niacin will continue to be less than enough to provide an adequate factor

TABLE 2—Low Income American Diets of 1926 and 1891 (for Adult Men)

Working Man's Diet of 1926		Low Income Diet of 1891	
	Gm		Gm
Bread and cereals	509	Flour	509
Sugar and sweets	61.5	Sugar	30
Fats	5	Butter	7
Lean meat	5	Meat	12.5
Milk	2.5	Milk	50
Total	210	Potatoes	400
Other vegetables and fruits	35.6		

Calculated from data in appendix C. Cumulative R. O. The American and His Food (ed. by Chicago University of Chicago Press) 1941. Such a diet provides approximately 70 calories. Gm of protein 0.01 Gm of calcium 1 mg. of iron 1.71 international units of vitamin A 0.5 mg. of a corbic acid and 11 mg. of thiamine.

† Calculated from a fifth of the values given in Weekly Food Budget for a Family of Five (Philadelphia 1911) appendix F. Cumulative R. O. The American and His Food. Such a diet provides approximately 720 calories. Gm of protein 0.1 Gm of calcium 1 mg. of iron 1.21 international units of vitamin A 1 mg. of a corbic acid and 1.5 mg. of thiamine. The bread winner of the family probably received 700 calories. If the diet values for all nutrients should be increased by about 9 per cent thus raising the allowance of thiamine to 70 mg.

No allowance made for loss of thiamine in handling and cooking foods. Such losses are believed to lower the thiamine content of the foods as suggested by as much as 50 per cent.

at safety and even with flour and bread enriched the large amount of sugar probably interferes with a content in the average diet of satisfactory amounts of thiamine and several other vitamins and minerals.

USE OF SUGAR WITH OTHER FOODS ENCOURAGED

The suggestion of enriching sugar as is done with flour by adding the vitamins essential for the oxidation of carbohydrate is not regarded with favor. Critics of enrichment of flour have objected that many vitamins are removed from flour in its milling and only thiamine and niacin are restored. The apprehension has been expressed that such imbalanced restoration may be harmful. In the case of flour this criticism can successfully be answered. The other B vitamins of wheat appear to be more evenly distributed through the grain and thus are lost much less in milling. However in the case of sugar only traces of vitamins survive the process of refining.

The suggestion has been offered that sugar could be made more nutritious by combining it with the minerals and vitamins of milk.⁵ This could be accomplished by enriching it with deproteinized whey, which would provide the vitamins of the entire B complex and also minerals. Also it sugar could be always used only as a means of making highly nutritious foods like milk or whey more appetizing much less odium would attach to it than does. Some candies contain appreciable amounts of powdered milk. Other candies carry nuts. Some cake is rich in egg and milk. Malted milk and chocolate flavored skimmed milk drinks provide considerable nutritive value from the milk or skimmed milk which they contain. When sugar is consumed it would be well if it was taken in the form of mixtures such as these that bear important nutritive values. But even here one is essentially "dining with calories," the food which is sweetened.

Accurate information is not available as to what proportion of the total use of sugar is for use with other foods. However, much sugar is consumed in candies, some prepared desserts and sweetened beverages which carry nothing of nutritional significance except sugar. Estimates of the consumption of candy show that it may be as great as 16 pounds (7.3 kg.) per person each year. Much of this candy is consumed by children and adolescents. Figures are available on sales of sweetened beverages.⁶ They indicate that manufacturers of such beverages

⁴ Wilder R. M. Nutrition in the United States. A Program for the Present Emergency and the Future. *Ann. Int. Med.* 11: 2189 (June) 1941.

⁵ N. W. Ayer & Son, Inc. Personal communication to the Council.

produced over eighteen billion 6 ounce bottles of soft drinks in 1939. It is also admitted that since 1939 the consumption of soft drinks has increased by from 20 to 30 per cent. From such data it appears that the per capita consumption of soft drinks must be in the neighborhood of more than three bottles a week per capita. According to data published by the Foodstuffs Division of the U. S. Department of Commerce⁶ the amount of sugar contained in "beverages, nonalcoholic" during 1939 constituted only 2.4 per cent of that used for all purposes. However, this figure does not include sugar added to beverages at the point of sale, and, on the basis of the data already mentioned concerning sales of sweetened beverages, the amount of sugar thus used figures out at approximately 12 per cent of the total. It seems obvious that, regardless of the method used to estimate the amount of sugar consumed as soft drinks, one obtains a result that is definitely undesirable from the standpoint of the nation's nutritional welfare.

WAYS AND MEANS OF LOWERING CONSUMPTION

The alternate approach to the nutritional problem created by sugar would be through effort directed at lowering its consumption. Because of war conditions this now is being done. Sugar rationing and its benefits to health will probably remain in effect for the duration of the war. The resulting benefit will be greater if, in rationing, priority is given to use of sugar as a sweetening agent for more nutritious foods. This has been recommended. The Food and Nutrition Board of the National Research Council has taken the position (1) that even a substantial curtailment of sugar is likely not to injure the nutrition of the American people, while other available foods can replace calories eliminated by sugar restriction, (2) that the use of sugar where small percentages make the more nutritious foods, such as bread and dairy products, more appetizing deserves high priority and should not be restricted, (3) that the use of sugar for preserving or flavoring other foods as in canning should be favored, and (4) that very considerable reduction of sugar in products which carry no other nutrients in considerable amounts, such as candy and soft drinks, would certainly not be deleterious to the nutrition of the public. The Council on Foods and Nutrition concurs in these views, which regrettably have not as yet been adopted in official rulings on the allocation of sugar.

Physicians presumably will continue to advise against the use of sugar between meals. Such advice should logically apply to the consumption of sweetened beverages as well as to the use of candy. Likewise action may be taken, as has been done with alcoholic drinks, to control the advertising of products, like candy and soft drinks, which tend to be used excessively by many persons to the detriment of health. There is merit also to the suggestion of Roberts⁷ that attempts be made through school boards to place a zone around school buildings in which the sale of candy and soft drinks would be prohibited.

Current views as to the exact cause of dental caries are numerous and divergent. Published summaries of findings and conclusions relating to the causes and control of this disease⁸ reveal that many investigators attribute harmful effects to the excessive consumption of highly refined carbohydrates. Without question overuse of sugars and starches will lessen the ingestion of foods which are needed for the maintenance of normal nutrition. Faulty nutrition is not desirable from the standpoint of the teeth or of the other body tissues. It is therefore to be expected that dentists as well as physicians will continue to advise against excessive use of sugar in the diet.

EXCESSIVE USE OF SUGAR BY CHILDREN AND WAR WORKERS DEPLORED

The figures given for the per capita annual consumption of sugar and those for sales of carbonated beverages, are average figures. People, however, do not eat averages, and diets vary from those containing very little to those containing very much of any item, be it butter, bread or milk. A disproportionate

amount of candy and soft drinks is consumed by children, and the advertising of candy and soft drinks usually makes a play for sales to children. The Council has received numerous inquiries from teachers and others asking for guidance in the problem presented by sales of sweetened carbonated beverages in the schools. The anxiety expressed in such letters has mostly been on the score of the caffeine content of some of these beverages. The use of caffeine by children is not considered wise, but equally undesirable as the writers of some of the letters have sensed, is the fact that the use of sweetened drinks and candies displaces the use of other foods. The sweetened drinks tend to replace milk, and candies the solid foods—meats, vegetables, fruits and grain products—that make up a nourishing meal.

It is obvious that a school lunch suffers gross deterioration when the beverage chosen in place of milk is a solution of sugar in flavored water. It also is generally conceded that excessive sugar eating between meals, or sugar eaten in smaller amounts within an hour of the regular mealtime impairs the appetite for food at meals.

Another place where a disproportionate consumption of sugar in the form of candies and sweetened carbonated beverages may lead to incalculable harm is the industrial plant engaged in war production. The Committee on Nutrition in Industry⁹ has reported that, in the great majority of these plants food dispensaries, where they exist, are operated on the "we give the men what they want" policy and that candy, pies, cakes and soft drinks are apt to constitute too great a proportion of their stock. The same report contains the following quotation from Haggard and Greenberg,¹⁰ who emphasized that food taken between meals is an integral part of the diet as a whole. They stated:

"The energy content of the food given at two between meal feedings (in industrial plants) might amount to 300 to 400 calories and thus constitute 15 per cent of the total intake of food. It was further evident that the diets of many of the employees were actually deficient in vitamins and minerals, or verged on such deficiency. Supplementary feedings with foods containing only carbohydrate further exaggerated these deficiencies. This feature of supplementary feedings constitutes the only valid criticism against eating between meals" which otherwise serves to alleviate much tiredness and decreased productivity in factory workers.

To obviate such criticism of between meal feedings the food selected, including beverages, should make satisfactory provision of minerals and vitamins as well as of calories.

Between-meal consumption of sugar in the armed forces is less disadvantageous than it is in industry because the rations in the army and the navy are closely supervised and provide a liberal supply of vitamins. However, even with soldiers and sailors supplied with satisfactory rations the tendency to say in effect "Let's give the boys what they want. It isn't going to hurt them," if allowed to go to the extent of permitting indiscriminate use of soft drinks and candy will undermine efficiency. Indiscriminate and uncontrolled supply of poor food for between-meal eating cannot be condoned with impunity anywhere.

COUNCIL OPINION

In view of the several considerations here recounted, it is the opinion of the Council that the present restrictions in the use of sugar will help improve the nutritive quality of American diets. From the health point of view it is desirable especially to have restriction of such use of sugar as is represented by consumption of sweetened carbonated beverages and forms of candy which are of low nutritional value. The Council believes it would be in the interest of the public health for all practical means to be taken to limit consumption of sugar in any form in which it fails to be combined with significant proportions of other foods of high nutritive quality.

THE SUPPLY OF PHYSICIANS

On October 29 Senator Claude Pepper of Florida, chairman of the Subcommittee on Manpower of the Committee on Education and Labor of the United States Senate, made public release of the report of his subcommittee on the supply of physicians for the armed forces and the civilian population. Thus a subject which has been given for some years careful and sustained consideration by some of the best informed and capable minds in the field concerned was thrown into the arena of public discussion. The evidence is lacking that representatives of the personnel divisions of the Army and Navy Medical Departments, the Procurement and Assignment Service for Physicians, Dentists and Veterinarians or the various agencies of the American Medical Association were called by the subcommittee for information before it offered to the people its views on the subject. Indeed the statement issued by Senator Pepper's committee indicates a lack of information as to what has already been accomplished by the agencies concerned in their endeavors to meet the needs of the situation. For instance the report says,

It is the committee's opinion that an over-all civilian authority should be established at once to supervise and control the drafting and recruiting of doctors. Until this authority is actively functioning, no recruiting of doctors for the armed services should be permitted.

This authority should immediately conduct a census of all doctors, both those already serving in the armed forces and those still in civilian life. This census should be careful and detailed. It should include a study of the distribution of physicians in civilian communities so that we may know at once what are the minimum needs of each area for medical care and whether these needs are now fully met, oversupplied or undersupplied in both optimum and minimum terms. We should have firmly fixed in mind the irreducible minimum of medical care needed to prevent disease and epidemic in civilian America, including war plant areas.

Had Senator Pepper's committee made inquiry, it would have discovered that the inventories proposed were made by the American Medical Association in 1940 and by the Procurement and Assignment Service in 1941 and that studies are made week by week of

the distribution of physicians in civilian communities as the committee proposes. What could the committee have had in mind in proposing that recruiting of physicians for the armed forces be halted regardless of the needs of those forces for medical services? The least that the nation can do for those who offer their lives in combat is to provide them with the utmost that medicine can offer for the alleviation of the wounded and the prevention of unnecessary death.

During the past month articles have appeared on this subject by Dr. Thomas Parran in *This Week Magazine*, by Michael M. Davis in *Harper's* and by an unknown editorial writer in the *New York Times* supporting the proposal that some federal agency be given authority to redistribute the medical profession. Mr. Michael M. Davis expresses the hope that "the Public Health Service will have been given the long delayed authority to act as well as study" by the time his article appears in print. Dr. Parran says in his article:

As a first step toward making the most of what we shall have left when the armed forces have been supplied with doctors and nurses, it would seem advisable for the War Manpower Commission to ration medical manpower just as the Office of Price Administration rations other essentials of civilian life, so that everybody may have something instead of some people having nothing.

Certainly the medical profession should know now that such forces seem to be urging regimentation of the medical profession by a federal agency. They seem indeed to be demanding authority over the medical profession quite beyond the range of any activities granted by the Congress of the United States to the War Manpower Commission or any other agency over any other profession or trade.

Under the auspices of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians a meeting has been called for this week in Washington to which representatives of all of the agencies intimately concerned with this problem have been invited. From this meeting should come positive action leading toward solution of some of the difficult problems that have been raised. In the meantime there might be a truce on the launching of some of the peculiar proposals that emanate from uninformed sources as a means of solving these problems. The taking of women physicians into the Army, as is proposed in one place, will certainly not make available more physicians for civilian communities. The utilization of interns and residents for the care of the civilian population, as has been proposed elsewhere, would merely deprive the Army of the physicians in the age group most needed. Furthermore, there is no evidence that the doctors who have hesitated to enlist in the Army and Navy Medical Departments would be any happier under theegis and control of the United States Public Health Service. The professional and intellectual attainments of physicians who have offered themselves to the Army and Navy, taken as a whole, are of the finest quality, is

there any reason to believe that these physicians would be more attracted to any of the nonmilitary federal services that employ physicians?

The Procurement and Assignment Service was created by the President of the United States and charged with consideration of the task of meeting the needs for physicians of the armed forces, industry and the civilian population. It has approached the problem scientifically, with accurate inventories of physicians available and needed and with due regard for the health of all the people of the United States. At the same time the concept that the winning of the war must be our first objective has not been overlooked. Actually what has been done in relationship to medical services might well serve as a model for the other activities of the War Manpower Commission.

EPIDEMICS AND SHIFTS IN WARTIME POPULATION

This war has already created more shifts of masses of population than have ever occurred before in human history. The effects are not all apparent as yet nor will they be even on the cessation of hostilities. However, one important aspect of this collateral effect of total war has been discussed recently by Maxcy,¹ namely the consequences of these changes on the problem of infectious disease.

The alterations in distribution of population and conditions of living have been brought about mainly by movements of three different kinds: (1) migration of able bodied men of military age from every walk of life and section of the country into induction and training centers of the Army and Navy, (2) evacuation of civilian population groups from areas of military importance and (3) migration of workers and their families into boom towns adjacent to military and industrial establishments. Each has its peculiar epidemiologic implications. As far as the mobilization of the armed forces is concerned, the experiences in this war have been much more favorable than in the last. This may be due, in part at least, to compliance with the principles of gradual mobilization urged by Zinsser² shortly before his death. In any event, Maxcy feels that the period of greatest danger from the common infectious diseases for the mobilized military personnel would seem to be past.

There has been little experience in this country regarding the evacuation of civilian population groups from areas of military importance. The resettlement of the Japanese families now in process is scarcely large enough to offer a fair test. In England, however, during the first week of September 1939, when war was imminent, more than one and one-fourth million mothers, children and cripples were removed principally

from urban areas to rural homes. Overcrowding of living conditions was inevitable. Although the effects are still not entirely clear, it is known that the incidence of diphtheria and scarlet fever actually decreased two thirds and poliomyelitis one third during the four months immediately following the evacuation from London as compared with the same quarter in the previous year. The experience with the other common communicable diseases was similar. However, removal of some 30 per cent of the children under 15 from evacuation towns, coupled with closure of the schools, was followed by a fall of 40 per cent or more in the rate of diphtheria among the children who remained, compared with a fall of 9 per cent in the "neutral" or unchanged areas, by the first quarter of 1940. Secondly, the influx of children drawn from these towns to reception areas with consequent increase in their population at ages under 15 by about 30 per cent was followed by an immediate rise of diphtheria among the native children amounting to 60 or 70 per cent as measured by notifications, but the rate in the whole population of children in these areas (native and visitor) declined again within six months to its original level. In any event the epidemiologic picture was much better than could have been anticipated.

In the United States the third kind of population movement, Maxcy says, has been most important up to now—the migration of labor. It has been estimated, for example, that six hundred thousand workers will leave the farm in 1942. Thus, in a sense, the rural districts have become evacuation areas and certain towns and cities have become reception areas. The movement has been one of adults to a greater extent than of children. The migratory war workers have been living in tents, trailers, dormitories, barracks, warehouses, basements and attics. Families have shared homes, apartments, even beds. Crowding in many areas has become intense. The effect on epidemiologic disease of this crowding, however, has varied.

In the case of Halifax, Nova Scotia, the prewar stabilized population of about sixty thousand increased rapidly with the onset of war. The epidemiologic implications were evident—crowding, a shifting immunity status and the possibility of the introduction of new strains of parasitic micro-organisms from Europe or elsewhere. For ten years previous to the war, diphtheria had prevailed in that city at a low level and there had been no active campaign to immunize the child population. Indeed, the Schick surveys made in 1940 and 1941 indicated that 80 per cent of selected groups of adults, as well as children, were susceptible. In September 1940 cases of diphtheria of unusual severity appeared. In the civilian population 588 cases were reported, and 303 cases occurred in the military forces. Aggressive measures were undertaken and the situation improved. This exemplifies the experience of a city in which the epidemiologically expected happened.

1. Maxcy, K. F. Epidemiologic Implications of Wartime Population Shifts. *Am J Pub Health* 32: 1089 (Oct.) 1942.

2. Zinsser, Hans. On the Medical Control of Mobilization. *Mil Surgeon* 87: 214 (Sept.) 1940.

In the Norfolk-Newport News area, however, the same rapid development of industrial, military and naval establishments occurred with similar crowding. In fact, the crowding was so severe that rationing of water was necessary for a number of months. Nevertheless, significant increase in infectious diseases was not reported up to the time of Macey's report. By way of explanation for this unexpectedly favorable epidemiologic result, Macey suggests that the population shifts in this country have occurred with gradually accelerating tempo and there have not been as yet convulsive evacuations such as those which occurred when the countries of Europe were engulfed in war with lightning-like rapidity. Furthermore, the start of these population shifts was made from a position "more favorable than has ever been realized before by any great nation in the health and welfare of its people."

The epidemiologic advancement is especially significant with regard to the intestinal infections, such as typhoid and dysentery, which have been minimized because of improved environmental sanitation and the decreased frequency of healthy carriers of intestinal pathogens. Furthermore, artificial immunization against smallpox, diphtheria and typhoid now protects a far larger proportion of the people than previously. Even the venereal diseases have received extensive attention and constitute a special problem on which intensive efforts already have been expended. There remain, Macey says, certain respiratory infections whose spread cannot be prevented and against which there are no means of artificial immunization. Two factors, perhaps, explain why this group has not reached epidemic proportions in spite of epidemiologically favorable conditions. In the modern United States, few communities can any longer consider themselves isolated in any real sense of the word. Exposure to common infections must therefore be at an earlier age, and relatively few persons escape attack in childhood. During this period an increasing proportion of the population have acquired better habits of personal hygiene. Promiscuous spitting, sneezing and coughing in public places have been reduced. The use of paper drinking cups has become popular.

The favorable epidemiologic picture in the United States is a credit to public health authorities but may constitute a fortunate accidental occurrence the explanation for which is not yet apparent. As Macey points out, the potential hazards in the immediate future would seem to be principally from viruses and bacteria with which we are already familiar and especially those which are parasites of the human respiratory tract. Today the human race is repeating many of the mass epidemiologic experiences which were experimentally observed in mice by Major Greenwood and his colleagues³ over a period of many years.

Current Comment

HEIGHT AND WEIGHT OF TORONTO SCHOOL CHILDREN

An exhaustive height and weight survey of Toronto elementary school children¹ carried out by a group of Canadian medical and statistical investigators has recently appeared under the auspices of the Dominion Bureau of Statistics at Ottawa. The survey involved measurements of about 78,000 children in comparison with about 59,000 measured in 1923. A serious attempt was made to disentangle hereditary and environmental factors involving growth. However, the report states that this has not been entirely satisfactory, there is no incontrovertible evidence to disprove the possibility that children of relatively prosperous parents are taller because their parents, on the average, are taller, as well as through superior environment. The results of the study agree with those obtained in similar analyses of heights and weights of school children elsewhere. The tendency found in British and American surveys toward an increase in average height and weight of from 2 to 5 per cent in a generation is also demonstrated by the Toronto figures. The report points out the desirability of integration of these results with work done on nutrition, since it is important to establish precisely the range within which good or poor nutrition can affect heights and weights. This is especially vital in war time, its long term importance is stressed by the surprising correlation observed between backwardness at school and poor stature.

SUICIDES DROP IN WAR

Certain psychologic effects of the war plus the increased standards of incomes seem to be responsible for the fact that the death rate from suicides among the policyholders of the Metropolitan Life Insurance Company, after reaching an exceptionally low point in 1941 has dropped sharply during the present year. This condition is not peculiar to the United States, since the suicide rate in England has fallen consistently from 1939 to 1941. The suicide rate among males in 1941 was 15 per cent below that of 1939. Such German figures as are available likewise show a fall in the suicide rate of 30 per cent from 1939 to 1941. In the last war the downward trend began in 1916 and continued through 1920 with a decline of 20 per cent between 1917 and 1918. The Statistical Bulletin of the Metropolitan Life Insurance Company for September, from which these facts are taken, suggests the following explanation of this decline:

A national calamity acts as a unifying force. The needs of the country become of paramount importance, and the petty interests and difficulties of the individual tend to be forgotten in the urgent desire to aid the nation in a time of crisis. Many sensitive individuals whose lives seem to lack purpose become absorbed in rallying to the defense of their country. Men live for the present and worry less about the future especially as, during war new channels of activity are opened. The demands of the military forces for material cause a sudden spurt in production and money incomes. Thus economic and psychologic forces work together in the same direction for the benefit of the nation's state of mind.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

ARMY

SCHOOL FOR MEDICAL DEPARTMENT TECHNICIANS

The School for Medical Department Technicians, William Beaumont General Hospital, El Paso, Texas, is designed to furnish the Medical Department of the U S Army with a highly trained group of technicians. Each of seven divisions of this school—laboratory, dental, medical, pharmacy, surgical, veterinary and x-ray—is allotted a certain number of students monthly.

The so-called specialty groups, which are laboratory, pharmacy, dental, x-ray and veterinary, require three months to complete these courses, while the medical and surgical groups complete the courses in two months. The specialty sections have prerequisite requirements as regards educational background, these being high school graduate or college student or graduate. The medical and surgical sections require only a common school education. Following are some of the requirements for receiving a certificate of proficiency in the various sections.

LABORATORY STUDENTS

The laboratory student must be familiar with the use and care of the laboratory equipment and be able to prepare and care for solutions and perform routine urinalysis, blood chemistry, gastric analysis and certain special determinations, such as alcohol in the blood and urine and the sulfonamides in blood and urine. He must be able to prepare culture mediums and inoculate culture mediums in laboratory analysis, be able to stain and recognize the characteristics of pathogenic organisms, perform water and milk analysis and type pneumonia, be able to perform the Kahn test, the two tube Kolmer test and the colloidal gold and Wassermann tests, be able to do routine blood types, determine bleeding, clotting and coagulation time and recognize some of the immature cells, and be able to type blood and cross match for transfusions, determine sedimentation rates, make reticulocyte and platelet counts, recognize those parasites which are found in man, identify the different types of malaria, Leishmania, trypanosomes and filaria and identify some of the insects which are injurious and related to diseases of man.

DENTAL LABORATORY TECHNICIANS

The dental laboratory technician must be able to construct simple or routine prosthetic appliances and related work. He must be able to do bridge work, assembly, soldering and finishing, make dentures, both full and partial, and produce castings, waxing, casting and finishing, wrought clasps and lingual and palatal bar bending. No operative dentistry is being taught nor is chair assisting a part of the course in this section.

PHARMACY STUDENTS

The pharmacy section student on graduation must be proficient in handling the equipment and glassware of this section. He must be able to care for the drug stock, dispense routine stock prescriptions to the wards, do simple pharmaceutical arithmetic, including metric system, ratio and proportion and be conversant with the U S Pharmacopoeia, the National Formulary and other authorized textbooks. In addition, he must be able to dispense narcotics and alcoholic preparations and maintain a record book of these drugs.

X-RAY TECHNICIANS

The x-ray technician is required to maintain the register and filing of films, prepare all necessary solutions, take dictation and be familiar with the phraseology of radiography. He is able

to place patients in position for any kind of roentgenogram, assist in fluoroscopy, and be able to prepare and use the latest localization apparatus. He must be familiar with the manipulation of x-ray machines, both portable and stationary. He must also become familiar with the minor defects that arise in these machines and know how to effect minor repairs.

VETERINARY TECHNICIANS

The veterinary section students are divided into two classes, the medical and surgical veterinary technicians and the meat and dairy hygienists.

The medical and surgical veterinary technician is required to be familiar with the care and use of the instruments and apparatus of the veterinary dispensary, be able to take temperature, pulse and respiration of the animals, be able to care for and maintain a veterinary ward, prepare and feed special rations, administer medicines, orally and hypodermically, apply bandages and dress wounds, give enemas, be proficient in the simple methods of restraint of animals, prepare and care for all the records of the clinic, and prepare the animals for and assist at operations.

MEAT AND DAIRY HYGIENISTS

The meat and dairy hygienist must be familiar with all the interpretations of federal and army regulations pertaining to meat and dairy products, he must be able to make inspections of meat, including fish and poultry, and prepare routine records and inspection reports, be familiar with the sanitary requirements of the personnel, stock rooms, docks and trucks used in the storage and handling of foods.

SURGICAL ASSISTANTS

The graduate of the surgical section is required to be familiar with all the technics of the medical technician, but in addition he must be able to perform the duties of an assistant in the operating room and to work in the surgical ward and dressing room or surgical dispensary. He must have a thorough knowledge of antisepsis, asepsis and methods of sterilization.

MEDICAL TECHNICIANS

The medical technician must be able to take temperature, pulse and respiration, prepare and serve simple ward diets, be able to care for and maintain an ordinary ward, and be familiar with the cleansing and disinfection of ordinary ward equipment and sterilization of ward instruments. He must be able to give enemas and baths to patients, administer routine medication and hypodermics, act as a nurse in acute infectious and contagious cases, do catheterizations, maintain and operate special equipment of a medical ward, such as oxygen tents and apparatus for intravenous injections and hypodermoclysis and recognize and report on the condition of patients.

FURTHER WORK

This school is designed to care for eight hundred students. Each of the specialty sections accommodates from fifteen to thirty students per class and each has three classes: beginners, intermediate students and advanced students. The medical and surgical sections have a capacity of one hundred students each and receive two months instruction. During the first month, students in the two sections take the same courses. During the last month students in the medical section finish training as aids in the medical service of William Beaumont General Hospital while students in the surgical section receive two additional

weeks of training in their specialty, doing practical work in the hospital during the remaining two weeks.

About 10 per cent of students have been unable to complete the course—a small percentage considering the many walks of life from which these students come.

COMMISSION HUNDREDS IN MEDICAL ADMINISTRATIVE CORPS

The four hundred and eighty soldiers who graduated on October 17 from the Medical Replacement Training Center Officer Candidate School at Camp Berkeley, Texas, formed the largest class ever to be commissioned in the Medical Administrative Corps of the Army Medical Department. Col Frank B. Wakeman of the Surgeon General's Office, Washington, D. C., delivered the principal address. Brig Gen Roy C. Hefebower, commandant of the Medical Replacement Training Center and of the Officer Candidate School, presented the diplomas. The commissioning of trained officers in the Medical Administrative Corps is in line with War Department policy of relieving army doctors and dentists of administrative and training duties and assigning them to active medical work with field forces.

MEDICAL SERVICE DURING MANEUVERS

The evacuation hospital unit comprising physicians from City Hospital on Welfare Island, New York, was commended by Lieut Gen Walter Krueger, commanding the third army in October, for its efficiency and morale in handling more than 2,600 cases during recent maneuvers in Louisiana. Among these cases were 250 major operations performed in the field under canvas. The evacuation hospital is in command of Lieut Col Paul K. Sauer, formerly chief of the surgical staff at City Hospital, New York. The chief of the medical service is Lieut Col Philip G. C. Bishop and the chief of the laboratory service, Capt Eugene Roberts.

COURSES IN NEUROLOGIC SURGERY FOR ARMY DOCTORS

Twenty-five U. S. Army medical officers from various parts of the United States began a course of training in neurology and neurologic surgery at the University of Illinois College of Medicine, Chicago, September 28. Similar groups of army officers will be trained during the next few months. The course includes laboratory, clinical and lecture work at the Neuro-psychiatric Institute at the university and also clinical work at Cook County Hospital. The University of Illinois School of Medicine, Chicago, and Columbia University College of Physicians and Surgeons, New York, were the only schools chosen, according to the *Chicago Daily News*, for the special training of army officers in neurologic surgery.

NORTH CAROLINA EVACUATION HOSPITAL IN TRAINING

The evacuation hospital unit organized at Charlotte, N. C., by Dr. Addison G. Brenizer, reported for a period of training at the Lawson General Hospital, Atlanta, Ga., October 25. The one hundred and three nurses, twenty-five of whom are from Charlotte, will report there soon. The unit will also have three hundred and ninety enlisted men, including pharmacists, x-ray laboratory technicians and others trained in special work.

CHICAGO BEACH HOTEL TO BECOME HOSPITAL FOR AIR FORCE

The Chicago Beach Hotel, on Hyde Park Boulevard, Chicago, has been taken over by the Army and is being remodeled for use as a hospital for the air forces technical training commands. The hospital will care for students in the new army air forces radio school, with headquarters in the former Stevens Hotel on

Michigan Avenue, as well as those in other air forces schools in this area. The Chicago Beach Hotel was acquired through court order in the same manner in which the Stevens and Congress hotels, the Coliseum and other properties were taken over for the schools in Chicago. Col Joseph J. Mack, executive officer of the hospital, is reported to have said that all rooms in the former hotel will become rooms for patients containing two or three hospital beds, except those on the ground, mezzanine and third floors. The ground floor will become a receiving room for patients, the trunk room a medical supply room, the medical detachment personnel will have their mess hall in the former dining room and cocktail lounge at the south side of the hotel, and the large lounge off the main lobby will become a mess hall for patients.

PROMOTIONS, TRANSFERS AND REIN STATEMENTS AS SOURCES OF RECRUITMENTS

The War Department issued an administrative memorandum on October 15, returning to a recently issued Civil Service Commission departmental circular, which pointed out to heads of departments and independent establishments the value of internal promotion, transfer and reemployment as devices for solving the manpower shortage on the war program. The War Department heartily endorsed the point of view expressed in the Civil Service Commission departmental circular, reaffirmed its long established policy in encouraging the use of present government personnel in filling responsible positions and urged personnel officers to take every possible action to extend this program through the service. The War Department further stated that internal promotion, transfer and reemployment practices, when used in conjunction with adequate in-service training programs, will answer a large portion of the present personnel needs of the service.

MEDICAL TRAINING CENTER BUYS DEFENSE BONDS

The headquarters of the Medical Replacement Training Center, Camp Berkeley, Texas, Brig Gen Roy C. Hefebower, commanding, announced on October 19 that six of the training battalions had achieved 100 per cent participation in the purchase of war bonds by the pay allotment plan and that a total of 20,217 bonds with a maturity value of \$1,248,180, had been sold at this station to date.

ARMY PERSONALS

Lieut Col Alvin L. Gorby, formerly chief of Organization Branch, Plans Division Office of the Surgeon General, has succeeded Col Albert W. Kemmer as armored force surgeon at Fort Knox, Kentucky. Col Gouverneur V. Emerson, chief of the surgical service, Letterman General Hospital, San Francisco, has been transferred to new duties. Lieut Col Albro L. Parsons, M. C., U. S. Army, for several years executive officer at the Medical Field Service School at Carlisle Barracks, has been retired from active service, effective October 31, on account of disability incident to the service. Colonel Parsons served in the first world war and later as a member of the United States military mission to Berlin, and in the Philippines and Alaska, and was decorated by the king of Greece and by the king of Yugoslavia.

Major Chester S. Fresh, clinical assistant in medicine at the Louisiana State University School of Medicine, New Orleans, has been made commanding officer of the Station Hospital at Ginner Field, Manchester, New Hampshire.

Lieut Col George E. Armstrong, M. C., U. S. Army, assistant commandant and school director of the Medical Replacement Training Center Officer Candidate School, Camp Berkeley, Texas, has been promoted to the rank of colonel. Colonel Armstrong in the first world war was an enlisted man. He studied medicine after the war, graduating at the University of Indiana in 1925, in which year he was commissioned in the regular army following an internship at Letterman General Hospital, San Francisco.

CIVILIAN DEFENSE

THE CIVILIAN EVACUATION PROGRAM

The Office of Civilian Defense and the Office of Defense Health and Welfare Services have been working on a general program of evacuating civilians and maintaining them in reception areas in case of air raids or other enemy action. A joint committee from these offices has published Bulletin No. 1 and Evacuation Bulletin No. 2, which cover the policies and principles of the civilian evacuation program, the basic problem relating to planning for the voluntary evacuation of designated groups of civilians, the making of surveys to discover the suitability of communities for reception in relatively safe sections of the country, and arrangements for the supplementing services and facilities during removal and after relocation. Evacuation Bulletin No. 2 does not cover detailed plans for emergency shelter on the day of a disaster or for possible rehousing of parts of the population in areas surrounding large military objectives. The plans for emergency shelter will be covered in another bulletin.

The joint committee on evacuation comprises the director of the Office of Civilian Defense as chairman, a representative of the Office of Defense Health and Welfare Services as secretary, and representatives not only of these offices but also of the Children's Bureau, the Public Health Service, the Office of Education and the Social Security Board. The material developed by this committee is made available to appropriate state and local officials through the regional directors of the Office of Civilian Defense. A member of the staff of each regional director, recommended by the joint committee, will be appointed by the director of the Office of Civilian Defense to develop evacuation plans in cooperation with state and local officials and the military authorities.

THE U S CITIZENS DEFENSE CORPS

The Citizens Defense Corps consists of six services each headed by a chief who is responsible directly to the commander of the corps. The six services are the wardens service, emergency police service, emergency fire service, emergency medical service, emergency utility service and emergency public health service, and now in Operations Letter No. 76 of the Office of Civilian Defense, Washington, D. C., dated September 21, it is recommended that an emergency welfare service also be created. The emergency welfare service will include those types of service and assistance provided to meet the social or economic needs of civilians which result from enemy action. These needs include emergency food and housing for those rendered homeless by attack and social services necessary to reestablish families and to get workers back to their jobs quickly. Provision should be made by the emergency welfare service for (1) registration centers to facilitate the reuniting of families, to extend advice and counsel and to answer inquiries, (2) temporary rest centers where food, shelter and other forms of emergency aid will be available immediately, (3) provision for rehousing families who have been rendered homeless, (4) cash assistance to those who have lost all immediate resources, (5) removal and storage of furniture and other effects from damaged buildings, (6) minor repairs to homes which can be rendered habitable, and (7) replacement of tools and working materials in order to return workers to a productive status. Government funds for assistance to civilians suffering from injury or loss will be made available to the appropriate state and local agencies, according to plans formulated by the Federal Security Agency in the Office of Civilian Defense and Welfare Services. The establishment of the emergency welfare service does not amend the agreement between the American Red Cross and the Office of Civilian Defense dated May 18, 1942.

The regulations (No. 3) of the Office of Civilian Defense relating to the U. S. Citizens Defense Corps have been revised by amendments which became effective September 1. The principal changes in the regulations are set forth in Operations Letter No. 34, Supplement No. 3 dated September 11. The Office of Civilian Defense on October 13 sent a memorandum to regional directors interpreting Supplement No. 3 with respect to responsibility for training. Basic training it was said is

necessary prior to enrolment in the U. S. Citizens Defense Corps, and the standards for this training are established by the U. S. Office of Civilian Defense. The various states through their counsels of defense may adopt the training courses in conformity with those standards as a minimum and where stated, to adopt such training plans, the completion of basic training under those plans will qualify registrants for acceptance in the Citizens Defense Corps. The commander of the U. S. Citizens Defense Corps is directly responsible for the training of persons after their enrolment in the corps. The commander is responsible for the details of training and is expected to appoint training authorities to carry out the details. Where states have not adopted such courses as are referred to, local defense councils should adopt similar courses in conformity with the standards of the U. S. Office of Civilian Defense as a minimum.

THE UNITED STATES CITIZENS SERVICE CORPS

The United States Citizens Service Corps of the Office of Civilian Defense is an army of unpaid civilian workers mobilized to do the many civilian war jobs necessary to keep the home front strong. The Citizens Service Corps is responsible for leading the fight against inefficiency, insecurity and poor health within the community. Any one willing to give his spare time to volunteer war work on the home front may join the corps. To join, persons 16 years of age or over may register with the Volunteer Office of the local defense council which has the power to decide who should be admitted to the Service Corps in its community. The local Defense Council will require that candidates be qualified in one of three ways: (1) by completing a prescribed training course approved by the council, in preparation for a volunteer work assignment; (2) by completing a prescribed period of apprenticeship mutually agreed on by the agency using the volunteer and by the local Civilian Defense Volunteer Office; (3) by completing fifty hours of work for which no specific training course is required in a volunteer position approved by the local Defense Council through the Volunteer Office. Some persons will already have completed the required amount of work in an approved position and will thus immediately be eligible for membership in the Citizens Service Corps. The corps encourages to the fullest extent the work of established agencies. The service opportunities for the Citizens Service Corps in general include whatever volunteer work—outside of civilian protection—the community needs to prepare itself for war. The members receive instruction from and work under, the supervision of the community agency or committee of the Defense Council to which they are assigned. Clerical workers are needed in practically all divisions of the corps. They may take the training course for the unit in which they are serving but are not required to do so. It is assumed that the volunteer work in the corps which professional people will perform are parallel with professional service in that field and their training, therefore, if any, will be of a refresher nature. A person who enters the corps by completing an approved training course and who fails to give community war service will not be allowed to continue in membership. The insignia of the corps consist of a red block V placed in the center of a white triangle, a red C and a red D placed respectively to the left and the right of the V and half its size and the white triangle embossed on a circular field of blue. Each appointee shall take an oath to defend and uphold the Constitution of the United States and to perform properly all duties of a member of the Service Corps. He shall then be entitled to wear the insignia of the corps until his membership is terminated. The Office of Civilian Defense, Washington, D. C., has published a handbook for the use of persons desiring to volunteer in the community war services, defense councils and the volunteer offices, and agencies using the services of volunteers.

CIVILIAN DEFENSE APPOINTMENTS

Dr. Felix J. Underwood, state health officer of Mississippi, has been appointed state chief of Emergency Medical Services, according to the *Jackson Clarion-Ledger*.

SUPPLIES FOR EMERGENCY MEDICAL UNITS

Medical and surgical supplies and equipment for emergency medical field units and casualty stations are to be shipped from the Office of Civilian Defense depots by direction of the Procurement Section of the U. S. Office of Civilian Defense. Because of their perishable nature, drugs, medical supplies and equipment will be shipped to hospitals for storage and subsequent disbursement to medical field units and casualty stations of the Emergency Medical Service. On arrival of the shipment at a hospital, the local property officer will check the shipment and see that it is properly stored by the hospital. He is then

authorized to transfer the property custodianship to the chief of Emergency Medical Service on certification that the property will be issued only to the emergency medical units of the U. S. Civilian Defense Corps. All property, whether stored at the hospitals or distributed to casualty stations or medical field units, remains the property of the government of the United States and due care is to be taken by all members of the Emergency Medical Service to safeguard it against loss or destruction. Additional information concerning the disposition of medical and surgical supplies by local property officers appears in instructional Letter No. 29 revised, dated September 18 and in a memorandum from the Office of Civilian Defense, Washington, D. C., dated September 11.

MISCELLANEOUS

THE STUDENT LOAN FUND APPOINTMENTS

Paul V. McNutt, Federal Security Administrator, announced on October 10 the appointment of Kendrick N. Marshall, former president of Chevy Chase Junior College of Washington, D. C., to direct the new student loan fund program. Mr. Marshall will administer the \$5,000,000 loan fund provided by Congress to enable students to complete their technical or professional education in fields essential to the war effort. He will be assisted by Ralph C. Flynt, formerly of the Education Division of the Civilian Conservation Corps, who will act as one of four liaison agents between the participating colleges and universities and the Office of Education. Rosa Lee Walston, formerly dean of women at Alabama Polytechnic Institute, will have charge of aid for women students. Ruth Grout, a graduate of the School of Public Health at Yale University and formerly supervisor of health education at the Tennessee Valley Authority at Knoxville, Tenn., has been appointed consultant in health education.

ELIGIBILITY FOR C RATIONING OF GASOLINE

The Office of Price Administration in announcing on October 26 that the eligibility for C rations of gasoline will be generally tightened under nationwide mileage rationing, made public a list of twenty preferred mileage uses. Among the twenty preferred mileage users listed are physicians, surgeons, dentists and midwives for making necessary professional calls outside their offices if they regularly make such calls or for transfer between offices maintained by them, but only if the applicants are licensed as such by the appropriate governmental authority; farm veterinarians for rendering professional services at agricultural establishments if the applicants are licensed by governmental authority and regularly render such professional services; medical interns, students of accredited medical schools or public health nurses (but not including private nurses) employed by or serving under the direction of a clinic or hospital, governmental agency, industrial concern or similar organization for rendering necessary medical nursing or inspection calls, duly authorized religious practitioners, other than ministers, serving members of an organized religious faith in the locality which they regularly serve, but this does not include travel from home to place of worship; workers, including executives, technicians and office workers, for necessary travel to, from, within or between military and hospital establishments, public utilities and industrial, extractive or agricultural establishments essential to the war effort for purposes necessary to their function or operation (this does not include travel for sales, promotional or certain other purposes) and members of the armed forces of the United States or state military forces on official business, where no military vehicle is available or for necessary transportation between home and post of duty (but not for transfer from post to post).

While the present Eastern gasoline rationing plans list only fourteen groups of preferred users the eligibility field actually has been narrowed in several instances and broadened in only a few minor categories. The Office of Price Administration

explains that the increase in the number of eligible groups results mostly from splitting up present groups for purposes of clarification.

PLAN TO INCREASE RECRUITMENT OF STUDENT NURSES

The urgency of the need for nurses was brought to the attention of the board of directors of the General Federation of Women's Clubs at a meeting in Chicago October 17, by Miss Katharine Fawcett, chairman national committee on recruitment of student nurses of the National Nursing Council for War Service. Miss Fawcett is reported to have said that fifty-five thousand nurses will be needed by next year, she appealed for the doubling of last year's bumper crop of student nurses enrolled in nursing schools. A plan whereby the General Federation of Women's Clubs would assist in the recruitment of nurses was presented at the meeting by Mrs. John L. Whitehurst. The women's clubs would contribute scholarships to nursing schools, poll their membership of two million for graduate nurses whom they would endeavor to have resume their profession set up student recruiting committees to cooperate with local nursing groups or state nursing councils, cooperate in the community plan for satisfactory distribution of available nursing service and organize Red Cross nurses and programs and home nursing classes in every women's club.

GOOD WILL NURSING TOUR

The Pan American Sanitary Bureau with headquarters in Washington, D. C., has sponsored a good will nursing mission to South American republics. The members of the mission, Miss Amelia Urquiza, Miss Herceila Rodriguez Brizuela and Miss Kathleen M. Logan, were scheduled to visit Mexico City, Guatemala, San Salvador, Tegucigalpa, Managua, San Jose and Panama City spending about a week in each place to familiarize nursing professions with the role of nursing in national defense, to explain first aid methods of the American Red Cross and to stimulate interest in nursing in women's organizations. Miss Logan was expected to remain in Central America as a public health nurse consultant of the Pan American Sanitary Bureau, while the other two members of the mission will return to Argentina, their home country.

VINYL ACETATE TO BE UNDER ALLOCATION CONTROL

The Office of War Information has announced that vinyl acetate used in the manufacture of rubber substitutes and in the synthesis of sulfonamide derivatives, was placed under complete allocation control, October 8, by the Director General for Operations. Allocation will take effect on November 1, according to the terms of order M 240, although the director may issue specific directions on use or deliveries after October 8. Deliveries of 25 pounds or less in any one month may be made without regard to allocation. Form PD 600 is to be used for requests for deliveries and Form PD 601 for reports from distributors.

ORGANIZATION SECTION

OFFICIAL NOTES

CHANGES IN RULES OF COMMITTEE ON AMERICAN HEALTH RESORTS

The Committee on American Health Resorts has made the following changes in its rules, which are herewith published by authority of the committee

W W BAUER, MD

CHANGES IN THE RULES

Former rule 6 was renumbered to become new rule 9

The following paragraph appearing in the introduction to the first edition of the rules was transposed to become

RULE 6—*Modifications of the Rules*—When any modifications of the rules are deemed necessary, those resorts already listed under rules as previously adopted will be notified promptly and will be given reasonable opportunity to comply with the modified ruling or voluntarily to withdraw from the listing

The following new rules were adopted

RULE 7—*Advertising of Health Resorts*—A health resort when listed will be permitted to make use in its advertising and descriptive literature of the phrase listed by Committee on American Health Resorts or the American Medical Association. No other phraseology shall be used, nor shall the name of the American Medical Association appear in any advertising or publicity matter except as included in this phrase. The fact that a resort is listed shall not constitute the principal feature of publicity, nor shall the fact of such listing be exploited

RULE 8—*Duration of Listing*—Listing of an institution shall on its first application be for a preliminary period of one year, subsequent listings shall be for a period of three years, all listings shall be subject to prior review in the event of violations of these rules

MEDICAL ECONOMIC ABSTRACTS

SICKNESS INSURANCE IN CANADA

According to a report of the executive committee of the Manitoba Medical Association, the movement for sickness insurance has advanced to the stage where discussions are going on between the Canadian Medical Association and the government. The Manitoba Medical Association adopted the following motion

That we instruct our representative on the executive committee of the Canadian Medical Association we are in favor of the medical profession in Canada cooperating with the government in devising a scheme to provide the benefits of modern medicine for all citizens of Canada whose income is not sufficient to provide it for themselves and the basis of the scheme should be medicine as at present practiced—patients to have free choice of a regularly qualified and registered medical practitioner

Shortly after the adoption of this motion, the deputy minister of health requested that the medical association appoint a committee to participate in the discussion. In 1941 the Committee on Economics of the Manitoba Medical Association, after gathering evidence from many other health schemes in Canada and the United States, suggested the following two plans¹

Plan 1 provides for surgical services only in a hospital for those with an income level at \$2,400 or less

Plan 2 provides for a complete surgical and medical service for members with an income limit of \$2,400 or less

These plans were presented to the Manitoba medical executive in November last and recommendations made that these plans be presented to the medical practitioners of Greater Winnipeg for criticisms. The profession expressed approval of the principles of these two schemes. It was then referred back to the Manitoba Medical Association executive meeting in January 1942, when the chairman was authorized to name four or five to select a provisional board

This provisional board, with Dr M R McCharles as chairman, reported progress and stated that three principles will guide the provisional board in working out the details. 1 This plan will not interfere with the professional relations between patient and doctor. It will take over the financial relations. 2 The provisional board will not countenance any procedure that will constitute a retrograde step in medicine. 3 That none of the fees on the schedules which are going to be drawn up will be below the present workmen's compensation board rates. He finally stated that there is much to do and that progress will be slow

THE HEALTH OF YOUNG PERSONS

Nearly 90 per cent of the 150,000 National Youth Administration youths examined by private physicians and dentists between January and October 1941 needed medical, surgical, nutritional or other care to improve their health or correct defects. This is the conclusion of "Health Status of N Y A Youth on Out of School Work Programs," which is the third and last in a series of studies based on N Y A examinations.¹ This document has been prepared and published by the National Youth Administration and the United States Public Health Service.²

The boys and girls examined were between the ages of 16 and 24, not attending school, from low income families and employed or seeking employment under the work program of the National Youth Administration. It is believed that they constitute a fair sample of American youths at low income levels and in search of work. A tabulation of the results of the physical examination placed 67 per cent in class A fit for any work or athletic activity. "Thirty per cent had health defects which limited their employability to some degree and put them in class B

"Three per cent were found to be temporarily or permanently unfit for N Y A employment and were placed in class C"

The proportions were much the same for male and female and for white and Negro youths. The greater prevalence of venereal diseases and tuberculosis ran up the proportions of Negro youths placed in class C. Hookworm was responsible for an increase in the number in this class in the East South Central and West South Central census regions

Health status appears to decline with age even among these young people. While 69 per cent of the group from 16 to 20 years of age were classified as fit for work, only 59 per cent of those from 21 to 24 could be included in this group. More city than country and small town youths had health defects which limited the kind of work they could do. There is a close resemblance between these results and those of the first million examined for selective service. In both groups dental and eye defects led the list of defects. Nose and sinus defects and tonsillitomy were next in importance. Roentgen examination was given wherever possible to positive reactors to tuberculin tests. Of 13,224 so examined, 16 per cent showed evidence of some stage of active tuberculosis

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ARIZONA

Dr Milloy Appointed Secretary of State Association—Dr Frank J Milloy, Phoenix has been appointed secretary of the Arizona State Medical Association, succeeding Dr W Warner Watkins Phoenix who resigned. Dr Milloy graduated at Northwestern University Medical School, Chicago, in 1920.

Health and Welfare Center Opened—The Pima County Health and Welfare Center, erected at a cost of \$45,000 has been opened in Tucson. The clinic space is divided into two large complete clinics with a waiting room between. Each has an examining room, two treatment rooms and a utility room. Facilities are now available for the staff, laboratory, storage room x-ray department, dentists office and a record room. Local and federal funds were used to defray the expense of the building.

CALIFORNIA

Changes in Health Officers—Dr Charles Bunniger Jr, city health officer of Oroville has been appointed county health officer of Butte County to succeed Dr Louis C Oller, Chico who resigned.—Dr William P Frank, Alhambra, has been appointed Alhambra District health officer. The Alhambra District includes El Monte, Monterey Park, San Gabriel, San Marino and South Pasadena.

New Professor of Hygiene at California—Dr Walter H Brown Stanford University who this year becomes emeritus professor of hygiene and physical education at Stanford University School of Medicine, is to become professor and chairman of the department of hygiene at the University of California at Berkeley. He succeeds Dr Robert F Legge who recently retired. Dr Brown graduated at Jefferson Medical College in 1906. He has been president of the American Public Health Association, health officer of Marion County Oregon and of Mansfield, Ohio where he conducted demonstrations for the Commonwealth Fund. He was also the first full time health officer of Bridgeport Conn.

Mental Hygiene for Adults—The University of California Extension Division is sponsoring a course in mental hygiene for adults in war and peace. The course opened on October 24 and will continue each Saturday morning until December 12. The speakers are Drs Jacob S Kanner San Francisco and Herbert E Chamberlain, Sacramento. The schedule is as follows:

Introductory Lecture on Mental Hygiene October 24
Mental Hygiene October 31
Psychological States and Their Emotional Components November 7
The Criteria of a Normal Personality November 14
Social Welfare and Security November 21
The Concept of the Neurotic Individual November 28
Treatment of Personality Difficulties and Maladjustments December 5
Joint Lecture—Special Problems of Civilian Morale and Personality Adjustment During War Period December 12

Prophylactic Stations—Three prophylactic stations have been opened in San Francisco under the auspices of the city and county departments of public health of San Francisco. They are at the Central Emergency Hospital, the Harbor Emergency Hospital and the Army Medical Station. The personnel for the station at the Harbor Hospital is furnished by the Twelfth Naval District and for the other two through the cooperation of the Fourth Army Headquarters. All supplies and equipment are furnished through the department of venereal disease of the San Francisco Health Department. The service at the stations is available to civilians as well as to members of the armed forces. During the first month of the operation of these stations 23 per cent of prophylaxis was administered to civilians. Arrangements have been made to distribute 500,000 leaflets advertising the location of these prophylactic stations to members of the armed forces. The Central and Harbor emergency hospitals are regular units of the San Francisco Emergency Hospital Service.

FLORIDA

New Children's Hospital—The new two story South Florida Children's Hospital, Miami, is rapidly nearing completion. The center part of the building is three stories in height. Ramps have been provided in the building to take the place of stairways. The hospital will contain two operating rooms and a plaster cast room. The hospital fills the need in this area for crippled children.

Personal—Dr Howard G Holland Leesburg, has been appointed medical consultant for the Florida Industrial Commission.—A dinner was held, October 12, to celebrate the completion of fifty years in the practice of medicine by Dr Henry L Palmer Tallahassee.—Dr Raymond D Tompkins, Mountam Home Penn, has been appointed chief medical officer at the U S Veterans Administration Facility, Bay Pines.

ILLINOIS

Dr Pettitt Returns to Private Practice—Dr Herbert L Pettitt Morrison, resigned on October 26 as assistant director of the state department of public health to return to private practice. According to the Chicago Tribune, Dr Pettitt explained that the shortage of physicians in his home city was the reason for his retirement from the department.

Chicago

Professor Shryock to Address Institute of Medicine—A joint meeting of the Institute of Medicine of Chicago and the Society of Medical History of Chicago will be addressed at the Palmer House November 27 by Richard H Shryock Ph D, professor of American history, University of Pennsylvania, and lecturer on history of medicine University of Pennsylvania School of Medicine Philadelphia, on 'Factors Affecting Medical Research in the United States, 1800-1900'.

Society News—The Chicago Society of Internal Medicine will be addressed on November 23 by Dr Italo F Volini, Robert O Levitt and Richard Martin Peoria, on 'Studies on Mercurial Diuretics Sudden Death Following Intravenous Injection Report of Three Cases with Electrocardiographic Studies Heinrich Necheles 'Depression of the Stomach by Nonspecific Substances and William F Peterson 'Medical Implications of Organic Rhythm Observed in Adult Triplets'.

New Foundation for Research in Hearing—The Parinly Foundation has been established at the Illinois Institute of Technology to carry on research in hearing. The foundation on which was erected through a trust fund of \$500,000 set aside by the late Samuel P Parinly Jr a Chicago businessman will concentrate its work on the physics of hearing and plans to cooperate with the medical profession on other aspects of the problem. This is in accordance with the plan of Mr Parinly who also stipulated that the research must be done at an institution of learning. The offices and laboratories of the new foundation which will begin its work at once will be located in the physics building on the south side campus of the Illinois Institute of Technology.

Professor Bensley Observes Seventy-Fifth Birthday—A symposium on 'The Physical and Chemical Organization of the Cytoplasm' will be held at the University of Chicago November 13 in honor of Robert R Bensley, D Sc, professor of anatomy at the university since 1907 in celebration of his seventy-fifth birthday. Participating in the symposium will be:

Dr Eliazar S G Burton
Harold W Berens Ph D Iowa City
Robert Chambers Ph D New York
Dr Albert Claude New York
Edmund V Cowdry Ph D St Louis
Isidore Cserh Ph D Baltimore and David Bodian Ph D
Dr Norwood I Hoerr Cleveland
Dr Arnold Lazarow
Dr Oliver H Lowry Boston
Alfred E Mirsky Ph D and Arthur W Pollister Ph D New York
Cordon H Scott Ph D St Louis
Francis O Schmitt Ph D Cambridge
Dr Kurt Stern New York

Dr Bensley was born in Hamilton Canada, Nov 13, 1867. He graduated at the University of Toronto in 1899, serving there until 1901, when he joined the University of Chicago as assistant professor of anatomy. The University of Toronto awarded him the degree of doctor of science in 1919. Professor Bensley, during the past ten years, has done pioneer work in separating a number of constituents from cytoplasm and has subjected them to chemical analysis. For more than thirty years he was director of the Hull Laboratory of Anatomy at the University of Chicago.

INDIANA

Medical Aspects of Chemical Warfare—The Indiana University School of Medicine, Indianapolis, in cooperation with the Indiana State Defense Council, held a symposium, October 23-24, on the medical aspects of chemical warfare. Real gases were used in the course. The use of gas masks was shown and their protection against tear gas was demonstrated by personal experiences. Animal tests illustrated the pathologic conditions caused by certain gases. The chemical warfare unit from Purdue University, Lafayette, staged field demonstrations of the dispersal of gases by means of explosives and the decontamination of gassed areas. The program included the following:

- Rolla N. Harger, Ph.D., Indianapolis: Physical and Chemical Properties of Chemical Warfare Agents
- Dr. Louis W. Spolyar, Indianapolis: Detection and Preventive Measures
- Dr. Frank Ferry, Indianapolis: Pathologic Changes Caused by War Poisons
- Dr. Khalil G. Wakim, Indianapolis: Physiologic Aspects of Chemical Warfare: Casualties, Respiration Following Gas Lung Injuries, Impairment of Body Efficiency While Using Gas Masks and Protective Clothing
- Dr. Harold M. Trusler, Indianapolis: Treatment of Injuries from Poison Gas
- Lieut. Col. William S. Keller, M.C.U.S.: Public Health Reserve, Columbus, Ohio, Why We Might Be Gassed and What Has Been Done About It
- Col. Willard A. Johnston, Lafayette: Demonstration of Gas Masks and Dispersion of Warfare Gases.

KANSAS

Society News—Dr. Louis B. Gloyne, Kansas City, discussed "Some Technics in Military Hygiene Which Can Be Used in Civilian Life" before the Wyandotte County Medical Society, September 1. Dr. Eldon S. Miller, Kansas City, addressed the society, September 15, on "The Aged Diabetic."

New Executive Secretary—Mr. Ralph Brooks, secretary of the chamber of commerce at Winfield, has been appointed executive secretary of the Kansas Medical Society, effective October 1. Mr. Brooks succeeds Mr. Clarence G. Munns, who has been commissioned a first lieutenant in the army air force. Mr. Brooks formerly was assistant secretary of the chamber of commerce at Wichita.

Examine Employees for Tuberculosis—The Sedgwick County Medical Society has approved a proposal of the state board of health to examine industrial employees in Wichita in an effort to detect the presence of tuberculosis. The state board is using a 35 mm. photo x-ray unit. The pictures are projected on a screen and all doubtful cases are reexamined on a standard 14 by 17 plate. When tuberculosis is suggested, the patient is sent to his family physician for diagnosis and treatment. Examinations are voluntary and will be given at the various plants on company time.

LOUISIANA

District Meeting—Drs. Edgar Hull and Robert C. Lowe, New Orleans, addressed the Seventh District Medical Society at Opelousas, September 10, on "Medical Aspects of Chemical Warfare Agents" and "Little Recognized Points in the Diagnosis of Nutritional Deficiencies" respectively.

MICHIGAN

State Medical Election—Dr. Claude R. Keyport, Grayling, was chosen president-elect of the Michigan State Medical Society at its annual meeting in Grand Rapids in September. Dr. Howard H. Cummings, Ann Arbor, was inducted into the presidency. Dr. L. Fernald Foster, Bay City, is the secretary and William J. Burns, Lansing, executive secretary. The seventy-eighth annual meeting of the state society will be held at the Statler Hotel, Detroit, September 22-24. The house of delegates will meet September 20-21. The session will be designated a postgraduate conference on war medicine.

Michigan Professors on Leave—Malcolm H. Soule, Sc.D., professor and head of the department of bacteriology and director of the Hygienic Laboratory, University of Michigan, Ann Arbor, has been on leave of absence since September. He was consultant to the director of the division of health and sanitation, coordinator of Inter-American Affairs at the Pan American Sanitary Conference in Rio de Janeiro, September 7-17, and will remain in South America until the end of November investigating the activities of the division in that continent, according to *Science*. Dr. Udo J. Wile, professor of dermatology and syphilology and chairman of the department at the University of Michigan Medical School, Ann Arbor, has been given a year's leave of absence to enable him to accept a commission as colonel in the U.S. Army. *Science* reports that he will serve as medical director in charge of venereal disease control in the U.S. Public Health Service.

MINNESOTA

New Committee to Study Medical Care—Three representatives each from the Minnesota State Medical Association, the state dental association, the state hospital association and the conference of social work compose a new committee to study medical care in Minnesota, fulfilling the object of a resolution passed in 1941 at the Minnesota State Conference of Social Work calling for an immediate study of the medical and public health situation in the state. Drs. George A. Earl, St. Paul, chairman of the committee on medical economics, Alfred W. Adson, Rochester, chairman of the committee on sickness insurance, and William A. Coventry, Duluth, chairman of the committee on low income and indigent problems, are the representatives for the state medical association.

Chiropractor Stolorow Sentenced—To Leave Minnesota—On September 29 Peter J. Stolorow, St. Paul, pleaded guilty in the district court of Ramsey County to a charge of criminal abortion. Stolorow stated to the court that all the members of his family are residing in California and that he desired a chance to leave the state of Minnesota permanently. According to the state board of medical examiners he stated to the court that it was impossible for him to keep out of the "abortion racket" in St. Paul because of his reputation for doing criminal abortions. The defendant was sentenced to a term of not less than two and not more than ten years at hard labor in the state prison in Stillwater. The sentence was suspended on condition that Stolorow immediately depart from the state and not return for any purpose whatever. Stolorow pleaded guilty on April 11, 1928 in the district court of Ramsey to a charge of criminal abortion and was sentenced to the state prison at Stillwater, serving over two years of this sentence. On April 15, 1935 he pleaded guilty to practicing medicine without a license and received a suspended sentence of one year in the St. Paul Workhouse. In May 19, 1941 he pleaded guilty to a charge of practicing healing without a basic science certificate and paid a fine of \$250. The same day he pleaded guilty to a charge of endangering the life of a minor and was sentenced to one year in the St. Paul Workhouse. Stolorow was formerly licensed to practice chiropractic and chiropody in Minnesota, but his basic science certificate and licenses were revoked in 1935.

MISSOURI

Dinner to Mr. Lewis Carris—Lewis H. Carris, LL.D., New York, director emeritus of the National Society for the Prevention of Blindness, was guest of honor at a dinner given in St. Louis October 10 by the St. Louis Society for the Blind in cooperation with the National Society for the Prevention of Blindness and the Association for Research in Ophthalmology. The Leslie Dana Gold Medal, awarded annually for achievements in the sight conservation movement, was presented to Mr. Carris at the dinner (*THE JOURNAL*, July 4, p. 821).

Changes in State Medical Association—At a recent meeting of the Missouri State Medical Association, Mr. Elmer H. Bartelsmeyer, St. Louis, executive secretary, was placed on a consultant basis subject to call and Mr. Raymond R. McIntyre, A.M., formerly of Fayette, was named acting secretary. Dr. Ralph L. Thompson, St. Louis, was made secretary-editor and Dr. Charles C. Hyndman, St. Louis, was made treasurer. Dr. William A. Bloom, Fayette, was elected chairman of the council to take the place of Dr. Curtis H. Lohr, St. Louis, who resigned because he was going into service.

NEW YORK

Teaching Day on Maternal Welfare—The state medical society sponsored a regional maternal welfare teaching day at Ellis Hospital, Schenectady, November 5 in cooperation with local health agencies and the state department of health. Dr. Alexander H. Rosenthal, Brooklyn, discussed "Local Anesthesia in Obstetrics and Gynecology" and Dr. Robert Gordon Douglas, New York, "Tocemias of Pregnancy."

Use of Sulfadiazine Discontinued—A news item in *THE JOURNAL*, October 17, page 546, announced the decision of the New York State Department of Health not to renew the supply of sulfadiazine to laboratory supply stations for the treatment of pneumococcal infections. A report has been received indicating that the news item should also have stated that "the vast superiority that was earlier claimed for sulfadiazine over sulfathiazole seems open to challenge and the markedly greater financial expenditure that the distribution of it entails seems hardly justified."

Staff to Continue Intern Education—The Samaritan Hospital Troy will continue its program of intern education with only two interns despite the hardships and pressure brought about by the war emergency. The required number of interns in residence at the 200 bed hospital is eight. One intern has been assigned to the service cases in the medical department and one to service cases in the surgical department. The attending physicians of other departments have assumed full responsibility for the detailed care of their cases, including private patients. This means that even senior attending physicians are on call for intravenous treatments, catheterization, transfusions and the like. The hospital believes that in this manner the interns are assured of ample time for the study and care of the patients.

New York City

Dr Emanuel Libman Honored on Seventieth Birthday—A dinner in tribute to Dr Emanuel Libman on the occasion of his seventieth birthday was held at the Waldorf-Astoria on October 31 under the sponsorship of the American Friends of the Hebrew University and the American Jewish Physicians Committee, organized for the purpose of building and maintaining the Medical Department of the Hebrew University in Palestine. Dr Nathan Ratnoff was toastmaster and the speakers included Dr Joseph H. Pratt, Boston, Col. Leonard G. Rowntree, Washington, D. C., Dr Morris Fishbein, Chicago, Dr Malcolm Goodridge, President of the New York Academy of Medicine, Dr Israel Strauss, Mr Samuel B. Finkel, Dr Siegfried J. Thannhauser, Boston, and Rabbi Stephen S. Wise. A bust of Dr Libman was presented to the Hebrew University on this occasion. Statements in tribute were received also from Albert Einstein, Princeton, N. J., and Chaim Weizmann. The three Nobel Prize winners present were Drs Karl Landsteiner and Otto Loewi and Otto Meyerhof, Philadelphia.

Blood and Plasma Exchange—A nonprofit organization has been formed under the sponsorship of the Medical Society of the County of New York with the approval of the Greater New York Hospital Association. It will be known as the Blood and Plasma Exchange Bank and will be under the direction of Dr Lester J. Unger. The organization will supply blood and plasma from hospitals with blood banks to hospitals requisitioning either one. The following seven hospitals with banks, which will be referred to as supplying hospitals, have joined the plan: Beth Israel, Lenox Hill, New York; New York Post-Graduate Medical School, St. Luke's and St. Vincent's hospitals; and Hospital for Joint Diseases. Blood and plasma, when orders are telephoned to the supplying hospitals, will be given to the messenger of the requisitioning hospital, whose delivery charges are paid by the requisitioning hospital. The rates charged requisitioning hospitals by supplying hospitals are: For 500 cc of blood or 250 cc of plasma \$20. For one-half of these amounts or less \$10. A hospital requisitioning blood or plasma may send two acceptable donors to the supplying hospital and thus cancel the entire charge of \$20 or may send one acceptable donor and cancel \$10 of the charge.

Care of Rheumatic and Cardiac Children—The cardiac classification service of the city department of health has undertaken the responsibility for the admission and discharge of children to special classes in the public schools. All children attending elementary public schools who are suspected of having heart trouble or recent rheumatic fever will be given a form to be filled out by their family physician or clinic physician. If the family has no physician or clinic affiliation, such a child will be referred directly to the cardiac classification service of the department of health. If, after examination, the cardiologist decides that the child has heart disease or has had rheumatic fever, he will discuss the condition with the parents and refer the child to some medical agency (private physician or clinic) for follow-up care and treatment. He will also assign the child to a school program. With few exceptions, it will be the policy of the cardiac classification service to recommend dismissal from school of all children with active rheumatic fever. In some cases home instruction will be recommended to admit children to health improvement classes for a short period of time (minimum of one school term) who have recently recovered from active rheumatic fever, to admit children to health improvement classes who have advanced rheumatic heart disease or congenital cardiovascular defects of sufficient severity to produce symptoms of cardiac insufficiency. The mere fact that a child has heart disease is not sufficient cause for admission to a special class. It is anticipated that many children will be admitted who do not have organic heart diseases. Other children who have heart disease or who have had rheumatic fever in the past (not very recent) will be placed on a modified activity program in a regular class. Emphasis will not be placed on the limitation of physical activity

in their daily school life, but rather on the avoidance of infection to prevent as far as possible recurrences of rheumatic fever. One rest period will be designed as one of relaxation in the school library or nature room, rather than one of repose on a cot or as is done in the health improvement classes. Another group of children will be permitted to attend regular classes, but will not be allowed to participate in a strenuous physical training.

OHIO

The Lower Lecture—Dr Alfred Blalock, professor of surgery, Johns Hopkins University School of Medicine, Baltimore, will deliver the annual Lower Lecture before the Academy of Medicine of Cleveland on November 20. His subject will be 'Surgical Shock'. The lecture is made possible by a fund donated by Dr William E. Lower, Cleveland, an honorary member of the academy and a former president.

Changes in Health Officers—Dr Norman S. Reed, Caldwell, has been appointed health commissioner of Noble County to succeed Dr Edward G. Ditch, Caldwell, who entered military service. Dr Kurt Carl Becker, Troy, has resigned as health commissioner of Miami County to enter private practice in Troy. He will be succeeded by Dr Harry Wain, Sidney, formerly health commissioner for Sidney and Shelby County.

State Medical Meeting Moved to Columbus—The annual session of the Ohio State Medical Association will be held in Columbus in 1943 instead of Toledo. The session will be held in the spring, provided war conditions will permit. The program will consist of a late afternoon or evening session of the house of delegates to be followed by a one day program of general sessions. Medical and health problems arising from the war and subjects related to the practice of medicine under wartime conditions will be the theme of the program.

Rheumatic Fever Reportable in Cincinnati—The Cincinnati Board of Health recently added acute rheumatic fever and rheumatic heart disease to the list of reportable diseases by physicians. The action was taken following a recommendation by the Heart Council of Greater Cincinnati to the Academy of Medicine of Cincinnati which in turn referred it to the board of health. According to the *Bulletin of the American Heart Association*, the purpose is mainly a statistical one in order that the heart council cardiologists and public health workers in the community may have more reliable information for study purposes.

PENNSYLVANIA

State Medical Election—Dr Augustus S. Keck, Altoona, was named president elect of the Medical Society of the State of Pennsylvania at its recent annual session and Dr Robert L. Anderson, Pittsburgh, was installed as president. Dr Walter F. Donaldson, Pittsburgh, was reelected secretary. The next annual session will be in Philadelphia, October 4-7.

Memorial Services for Physician Killed in Action—A special memorial service for Major James A. McCloskey, M. C., U. S. Army, who was killed in action in Bataan, P. I., was held at the chapel, Carlisle Barracks, Pa., October 14. Major McCloskey was graduated at the Medical Field Service School at Carlisle Barracks in 1937 and is believed to be the first graduate of the school killed in this war. He graduated at the St. Louis University School of Medicine and attended the Army Medical School, Washington, D. C. For a time he was a resident surgeon at the Nix Hospital, San Antonio, Texas.

Pittsburgh

University News—Herbert E. Lougennecker, Ph.D., has been appointed associate professor of biochemistry and associate director of the Buhl Foundation projects in the University of Pittsburgh during the absence of Charles Glen King, Ph.D., New York, who is on leave to serve as scientific director of the Nutrition Foundation, Inc.

Industrial Fellowships Established—P. Duff & Sons, Inc., has founded in the Mellon Institute an industrial fellowship that will be concerned with the scientific investigation of problems concerning cane molasses. The first fellowship was assumed on October 22 by Arthur J. Nolte, a food specialist, who has been working with the U. S. Bureau of Agricultural Chemistry and Engineering at Winter Haven, Fla.

RHODE ISLAND

Society News—A panel discussion of the clinical and sociologic aspects of rheumatic fever and its heart complications was presented before a joint meeting of the Providence Medical Association and the Children's Heart Association at Rhode Island, October 5. The speakers were Drs Henry E. Utter, chairman, William P. Buffum, Harold G. Calder, Francis V. Corrigan, Bance Feinberg, Frank T. Fulton, and John C. Ham. All are from Providence.

SOUTH CAROLINA

Society News—Dr. Albert B. Sabin, Cincinnati, major officer, addressed the Greenville County Medical Society recently in Greenville on "Recent Studies on the Natural History of Human Poliomyelitis."—Dr. Kenneth M. Lynch, Charleston, discussed "Abnormal Chromosome Growth" before the Columbia Medical Society, October 12.

Personal—Dr. William Cyril O'Driscoll has been promoted to associate professor of anatomy at the Medical College of the State of South Carolina, Charleston.—Dr. William C. Whitesides, York, was recently chosen president of the York Chamber of Commerce.—Dr. Gordon R. Westrope, director of the Cherokee County Health Department, Grifney, has been appointed director of District No. 2, including eleven upper state counties.

Refresher Course—The Alumni Association of the Medical College of the State of South Carolina sponsored a refresher course in Charleston November 4-5. The program covered a wide range of subjects and speakers included Drs. John B. Yonkins, Nashville, Tenn.; Udo J. Wilk, Ann Arbor, Mich.; Austin V. Deibert, Hot Springs National Park, Ark.; Luther I. Holt, Jr., Baltimore; Reginald Fitz Boston and Howard I. Karsner, Cleveland, who lectured at the Founders Day banquet on "Aortic Stenosis."

TEXAS

Baylor Adopts Accelerated Program—The faculty of Baylor University College of Medicine, Dallas, has voted to go on in accelerated program of instruction. The present session 1942-1943, will close on May 31, 1943. The next session 1943-1944 will begin June 21, 1943 and close March 13, 1944. Thereafter for the duration of the war a new class is to be admitted and a class graduated approximately every nine months.

New Health Center—The government has allocated \$140,000 to purchase and equip the eight story Alamo National Bank Building, San Antonio, to be used as a public health center. Of the \$140,000 \$80,000 will be used for outright purchase of the building and \$60,000 for equipment. The building will be the property of the federal government, and city and county health departments may rent space for \$1 a year. It is expected that all the facilities of the San Antonio health unit will be housed in the center, with the exception of the venereal disease clinic newspapers reported.

VIRGINIA

Personal—Dr. Garland M. Harwood, Richmond, has been appointed acting medical director of the Life Insurance Company of Virginia. Dr. Emmon S. Williams, Richmond, resigned as medical director to enter the navy medical corps.

State Medical Election—Dr. Claude B. Bowyer, Stonega, was chosen president elect of the Medical Society of Virginia at its recent annual meeting and Dr. John M. Emmett, Clifton Forge, was installed as president. Miss Agnes V. Edwards, Richmond, is the executive secretary-treasurer.

WASHINGTON

Health Districts Formed—The health departments of Jefferson and Clallam counties have united to form a joint public health district unit following a conference of the state department of health with officials of these counties and the cities of Port Angeles and Port Townsend. The central office will be located at the court house in Port Angeles with a branch office at Jefferson County court house in Port Townsend. District offices will be located in other sections of the counties.—Walla Walla, Franklin and Benton counties have combined into a tri-county health district with Dr. John A. Kahl, Walla Walla, in charge.

WISCONSIN

Personal—Dr. Dorothy Z. E. McDonald, Madison, advisory physician in school health education of the bureau of maternal and child health of the state board of health has resigned to become vice chairman of the department of public health of Loyola University Medical School, Chicago.

University News—Sister Elizabeth Kenny lectured at the University of Wisconsin Medical School, Madison, October 15 on "Treatment of Acute Anterior Poliomyelitis." The lecture was under the auspices of the Alpha Epsilon Iota Fraternity. Joseph C. Hinsey, Ph.D., New York, discussed "Regeneration of the Visceral Nervous System" at the school, October 13, under the auspices of Phi Chi.

GENERAL

Examinations in Obstetrics and Gynecology—The American Board of Obstetrics and Gynecology announces that the next written examination and review of case histories for all candidates will be held in the United States and Canada in November (THE JOURNAL, July 11, page 895). The part II examination will be held at Pittsburgh, beginning Wednesday, May 19 and closing Tuesday, May 25.

Josiah Lilly Awarded Remington Medal—Josiah K. Lilly, Ph.D., since 1898 chairman of Eli Lilly & Co., has been awarded the twenty-first Remington Medal of the New York branch of the American Pharmaceutical Association for his distinguished services to pharmacy. The committee of selection was composed of past presidents of the American Pharmaceutical Association. The presentation of the medal is expected to be made soon at a meeting of the New York branch.

Claim Adjuster Contracts Medical Service—A report has been received that a "Mr. John A. Mendoza" representing himself as the claim adjuster for Aetna Casualty Company of Hartford, Conn. and the Equitable Life Company of New York, out of the San Francisco office has contracted professional and personal bills and disappeared without payment. Letters from both companies deny that any such John A. Mendoza by name is or has been in their employ.

Army-Navy E Awards—The Army-Navy E award was presented to representatives of E. R. Squibb & Sons at special ceremonies in the Waldorf-Astoria Hotel, New York, September 18, by Rear Admiral Harold W. Smith, chief of the Navy's research division of the bureau of medicine and surgery, Washington, D. C. Representative insignia pins were given to employees. Similar ceremonies were held at the Abbott Laboratories, North Chicago, Ill., on September 22. Principal speakers included Rear Admiral John Downes, commandant of the Ninth Naval District and Col. Fredrick C. Rogers, commanding officer at Fort Sheridan. Dr. Morris Fishbein, Editor of THE JOURNAL, was master of ceremonies and Governor Green was guest of honor.

Cancer Study at National Institute of Health—Under the provisions of the National Cancer Institute Act of Aug. 5, 1937 the National Cancer Institute has offered, during the past five years, traineeships in the diagnosis and treatment of cancer to young physicians interested in clinical cancer work as a career. Fifteen men are now taking this course. Fifty have completed the course, which lasts from six months to not more than three years depending on the needs of the individual trainee and on the facilities and type of training offered by the training institutions. The stipend is, as a rule, \$6 per working day and may be slightly more under unusual circumstances. A few vacancies are still open to properly qualified young physicians, men or women who are interested in cancer but for some reason or other are not available for military service. For further information write to the National Cancer Institute, Bethesda, Md.

Low Suicide Rate—The *Statistical Bulletin* of the Metropolitan Life Insurance Company for September, in an article entitled "Suicide and War," indicates a record low suicide rate among its policyholders. This phenomenon of an exceptionally low suicide rate is attributed largely to the psychological effect of the war, although increased incomes have contributed a share. According to the *Statistical Bulletin*, a similar low level of suicide mortality is observed in England, where the rate fell consecutively from 1939 to 1941 and where the 1941 suicide rate among males was about 15 per cent below that of 1939. Also there was a sharp fall in the number of suicides in the last three months of 1939 which in England marked the opening period of the war. The bulletin states that the decline in suicide has been observed in practically every country at war and, in some instances, neutral nations neighboring on the belligerent countries shared in the same phenomenon. Our experience in the last war was, the bulletin states, not only a decline of 20 per cent between 1917 and 1918 but the downward trend began in 1916 and continued through 1920.

Centers for Teaching Kenny Method—Training facilities have been established for teaching the Kenny method in the treatment of infantile paralysis at the following places:

School of Health (Women) Stanford University, Calif.
Childrens Hospital Society, University of Southern California, Los Angeles
University of Minnesota, Minneapolis
Northwestern University Medical School, Chicago
D. T. Watson School of Physiotherapy, Lettsdale, Pa.
Physical Therapy Post Graduate School, Warm Springs

While Sister Kenny and her Australian assistants work only at the University of Minnesota, each of the other places has trained personnel in charge of the courses. The programs are conducted in cooperation with the National Foundation for Infantile Paralysis and information as to costs and dates of courses

and admission policies can be secured directly from the schools. The *National Foundation News* announces that plans are under way to add the seventh training center in New York which, it is hoped, will have courses available on December 1. The New York center will be carried on with the cooperation of several hospitals and schools of physical therapy under the direction of the Greater New York chapter.

Educational Program on Rheumatic Fever—A health education program on rheumatic fever and rheumatic heart disease will be initiated this fall by the Metropolitan Life Insurance Company. The crippled children's division of the U S Children's Bureau will cooperate through its contact with state rheumatic fever programs now being financed with social security funds. The project aims to acquaint the company's policyholders and the general public with what is definitely known about rheumatic fever and rheumatic heart disease and to acquaint the medical profession more fully with the modern concept of the disease, the methods most recently employed to insure proper diagnosis and treatment, and the efforts being made by public health authorities to control the disease. Specially prepared leaflets, speeches, radio broadcasts, news releases, cooperating programs before state and county medical societies and the publication of articles in certain periodicals will be among the means used to project the new campaign. The program is a continuation of the health education activities carried on since 1909 by the welfare division of the Metropolitan Life Insurance Company. Other recent campaigns have included those on pneumonia in 1937-1938, appendicitis in 1938-1939, whooping cough in 1940 and diabetes in 1941.

Industrial Hygiene Foundation.—The seventh annual meeting of the Industrial Hygiene Foundation will be held at the Mellon Institute, Pittsburgh, November 10-11. The tentative program includes the following list of speakers:

Hon Paul V McNutt Washington D C Manpower Conservation
Dr Leroy U Gardner Saranac Lake N Y Inhalation of Magnesium Dust
Dr James L Blaisdell Timmins Ont, Further Studies of Aluminum Powder in Combating Silicosis
Dr W Irving Clark Worcester Mass Data on the Use of Grinding Wheels
Dr Eugene P Pendergrass Philadelphia Practical X-Ray Techniques for Mass Physical Examinations
Dr Louis Schwartz Bethesda Md How to Prevent Dermatitis in War Industries
Francis R Holden Ph D New York What the Foundation's Plant Surveys Are Showing
Wattime Problems in Chemical Industries and Industrial Health Implications (speakers to be announced later)
Dr Huntington Williams Baltimore Health Problems in Suddenly Expanded Industrial Communities
Dr Stanley J Seeger Tearkana Texas Industrial Health Program of the Organized Medical Profession
William McK Bafar Sc D Leona N J Findings from Foundation Public Health Service Study
Dr John T Wittmer New York Some Common Causes of Sick Absences and Their Prevention
Dr Simon S Leopold Philadelphia The Cold as an Industrial Health Problem
Lieut Meyer Brown Chicago M C, U S Navy Role of Psychiatry in Absences
Ned H Dearborn Ph D New York The Accident Factor in Absenteeism

There will be two panel discussions: Fatigue in Wartime Industry with Dr Clarence D Selby, Detroit, Dr William A Sawyer Rochester, N Y, Nathaniel Kleitman, Ph D, Chicago and William C Forbes, LL D, Boston, as the speakers and Putting Women, Older Men and Physically Handicapped to Work with Dr T Lyle Hazlett, Pittsburgh, E P Chester, BS Hartford, Conn, and Mary Anderson, Washington, D C, as the speakers. There will also be talks on "A Practical Nutritional Program for Industry" and "Responsibilities of Management and Labor in Keeping Men at Work," speakers to be announced.

CANADA

Community Doctor Service—The Canadian Red Cross Society, Ontario Division, in cooperation with the Ontario Medical Association and the department of health, has inaugurated a community doctor service, which, according to the *Canadian Public Health Journal*, is an emergency wartime measure to assist rural and isolated communities to obtain the service of general practitioners. More than 25 per cent of the doctors of Ontario have gone into the forces or volunteered for other war services. A minimum of \$4,000 is guaranteed by the Ontario Division of the Red Cross. The basis of service is general practice. No extra fees can be charged for any 'added' service to the subscriber. The doctor provides his own transportation to the hospital, which must be within 25 miles. Patients supply their own drugs and supplies except in emergency or office care. Provision is made for a locum tenens for a two week holiday at the expense of the administration and for leave of absence for postgraduate study at the expense of the community doctor. As far as possible, the usual

patient-doctor relationship is maintained. Before the introduction of a new service and once each year thereafter a family to family canvass is made for subscribers by the local Red Cross. Although dues are paid on a per capita basis, families which choose to become subscribers must participate as a unit. However, reduced rates are offered to families with many dependent children, and no charge is made for the sixth and additional child. Families who do not subscribe in advance have to wait thirty days (maternity, nine months) for service. Non-subscribers are related to the plan only with respect to the guaranteed income. Emphasis on prevention arises from the prepayment feature and the appointment of the community doctor as medical officer of health. The doctor's duties are understood to include antepartum and infant welfare care, immunization and school health as well as the usual attention to municipal sanitation.

LATIN AMERICA

Rockefeller Fund Aids Campaign Against Malaria—The Colombian government has signed an agreement with the Rockefeller Institute for Medical Research, New York for financing, up to 3,700,000 pesos, a campaign against malaria and other tropical diseases, newspapers reported October 25. This serves the double purpose of improving public health and providing employment for many workers with the ultimate result of better production of essential products.

New Officers of Medical Societies—The new board of directors of the Sociedade de Oftalmologia de São Paulo, Brazil, for 1942-1943 was recently appointed with the following members: Dr W Belfort Mattos president, Dr Plinio Caiado de Castro, vice president, Dr Silvio de Almeida Toledo, secretary-general, Dr Renato de Toledo, secretary, Dr Francisco Amendola treasurer and Dr Jose Mendonça de Barros, general manager. The new board of directors of the Associação Médica do Instituto Penido Burnier of São Paulo, Brazil, was recently appointed with the following members: Dr Gabriel Oliveira da Silva Porto, president, Dr Penido Burnier Jr and Dr Cid Marques da Silva secretaries, and Dr Leoncio de Souza Queiroz treasurer. The heads of the editorial board of the *Arquivos do Instituto Penido Burnier* are Drs Penido Burnier, Guedes de Melo Jr and Monteiro Sales.

Resolutions on Vital Statistics—The Eleventh Pan American Sanitary Conference in session in Rio de Janeiro, Brazil, September 7-18 adopted two resolutions concerning vital statistics and which if carried out would make for a uniform recording by statisticians of various countries. One resolution urged the creation and maintenance in each of the American Republics as part of their health services of a technically adequate organization for the collection compilation and analysis of biodemographic data and other data related to public health. The resolution also covered the cooperation by the Pan American Sanitary Bureau with the Inter-American Statistical Institute and the statisticians of the various countries in establishing uniform methods and procedures. Another resolution urged the collection of statistical data relating to the incidence of cancer and cardiovascular diseases. It also recommended that the systematic practices of autopsies in case of death without medical assistance be intensified that, in the schools of medicine exercises in the proper certification of death be made obligatory in the course of hygiene and of legal medicine that a committee be established in the office of the Pan American Sanitary Bureau for the purpose of making uniform the standards of biostatistics and the coordinating of the efforts in the solution of biostatistics problems of common interest to the countries of America.

FOREIGN

Epidemic in India—The *New York Times* October 17 reports that one of the worst epidemics of malaria in history is present in New Delhi, India following the heaviest rains in many years. The *Times* in quoting the *Delhi Dawn* states that whereas 1,500,000 pounds of quinine is needed to treat present cases, Indian stocks amount to only 200,000 pounds.

CORRECTION

A Well Balanced Diet in Pregnancy—In the item in the London Letter of August 21 entitled 'A Well Balanced Diet in Pregnancy' (THE JOURNAL, October 3 p 385) the second paragraph should have concluded 'In 1,530 primigravidae who received the supplementary diet the toxemia percentage was 5.4, in those who did not it was 7.4. The result was striking and indicated a protection by the supplementary diet of almost 30 per cent.' The incorrect percentages used in THE JOURNAL article appeared in the original abstract received from the London correspondent.

LONDON

(From Our Regular Correspondent)

Oct. 3, 1942

Pregnancy and Women's War Work

In the war effort women are conscripted for the auxiliary services. Those doing essential work are not called up, and this includes women's most important work, the production and care of children. An enormous number of women have taken the place in industry which used to be filled by young men who have joined the fighting forces. Hence arises the obstacle of motherhood. Some firms send expectant mothers off duty for some weeks before and after labor and others do not. The law forbids factory work for four weeks after confinement, but not other work. The financial alternatives to ordinary wages are not sufficient to make women willingly give up their work. Yet the health of the mother during the last weeks of pregnancy and during lactation is of profound importance for the future of the country, especially in this time of threatened decrease of population. The National Council of Women has made representations to the minister of health on financial allowances for women during pregnancy and lactation. The council holds that a woman should be debarred from working in any paid employment during the last eight weeks of pregnancy and the first eight weeks of lactation. Under the National Insurance Act pregnancy is not recognized as incapacitating from work and therefore as qualifying for sickness benefit. But many of the societies allow payment of benefits during the last three or four weeks of pregnancy. The National Council of Women says that the war has aggravated a position which was previously unsatisfactory and suggests that the societies might interpret more widely their duties in paying insurance benefit to insured pregnant women. At the request of the minister of health the societies have agreed to relax their rules with regard to accepting women war workers as members. But the council asks them to go further by announcing that as a wartime measure they will recognize the last eight weeks of pregnancy as a period of incapacity within the meaning of the insurance act. But this would benefit only insured women, while others are equally in need of help.

Nursing to Be a Closed Profession

A nursing reconstruction committee set up by the Royal College of Nursing under the chairmanship of Lord Horder has submitted to the minister of health a report on the training, qualifications, employment and control of the assistant nurse—a problem which has given rise to more controversy than any since the passing of the Nurses Registration Act. The committee recommends that assistant nurses be enrolled under the General Nursing Council and that thereafter nursing become a closed profession, none but state registered, state enrolled assistant nurses and those training for such grades to be allowed to nurse for gain. The committee recommends that the two year training for assistant nurses (as compared with four year training for state registered nurses) should be taken chiefly in hospitals for the chronic sick, with some additional experience in fever, mental or tuberculosis hospitals. Candidates should not be expected to pass written examination but be given a simple practical and oral test at the end of their training, which must be essentially practical. They should not be instructed alongside nurses in training for the state registers, and, when qualified, their work must be supervised by a state registered nurse.

The committee recommends legislation making it an offense for nurses' agencies, which should in future be registered and inspected, to supply a nurse not on the state register. Inspec-

tion of nursing homes should be more vigorous. Private nurses should be obliged to notify their intention to practice and furnish the patient or his relatives with particulars of their qualifications.

Women Demand Equal Compensation for War Injuries

In support of the demand that women should receive compensation equal to that paid to men for war injuries, some eighty-four members of all parties propose to table in the House of Commons the following motion: "That this House is of the opinion that as women are now being conscripted for work in war factories and for fire watching they should be compensated at the same rate as men under the Personal Injuries (Civilians) scheme. The same argument will be advanced by a deputation, to be received by Mr. Atlee at the House of Commons, comprising many members of Parliament and representatives of a large number of women's organizations. Women members of the National Fire Service and the Civil Defense services, nurses and women war workers will be represented. The introduction of compulsory fire watching for women has led to increased insistence on the demand for equal compensation for war injuries.

A Hospital in Tobruk Under Siege

Mr. Ford, minister for the Australian army, has issued the story of the Australian general hospital during the siege of Tobruk. He described the work as one of the major achievements of the allied defense. When the fifty nurses were evacuated two days before the beginning of the siege they begged that at least twelve of them should be allowed to stay on to manage the wards and man the operating theaters, but the authorities refused, and inexperienced hospital orderlies took their places. These showed great aptitude and reached a satisfactory standard of efficiency in the operating theater in a week. Two of the best were an engine hand and a plumber. The operating theaters were huts and boiler rooms, and the surgeons discarded their sweat soaked gowns and worked in shorts, waterproof aprons and gloves.

At night the conditions were especially bad, the surgeons operating under a glaring electric light, with the windows blanketed for the blackout. The beach section of the hospital, dealing with casualties which did not require an operation, consisted of tents dug to a depth of 5 feet and protected with sandbags. The town section was situated in former Italian barracks, the thick walls of which provided protection from bombs. It was near many targets, such as anti-aircraft posts, which were repeatedly attacked. Some patients were killed in the hospital. In an initial air attack two medical officers, two orderlies and nearly a hundred patients were killed and many others wounded. But no one lost heart. Without the assistance of the navy it would have been impossible to carry on. Destroyers maintained a regular ferry service.

A Mold with Remarkable Antibacterial Powers

Thirteen years ago, Mr. Alexander Fleming, now professor of bacteriology in the University of London and director of the department of systematic bacteriology, St. Mary's Hospital, discovered that the mold *Penicillium notatum* had remarkable antibacterial properties. Research was continued at the school of pathology of the University of Oxford by Prof. H. W. Florey, who separated the active principle, which is now known as "therapeutic penicillin." This has been found to inhibit the growth of staphylococci completely in a dilution of 1 in 25 million and partially in a dilution of 1 in 160 million. An additional advantage is the harmlessness of the drug. In experiments on mice no ill effects were observed though large doses were given, and the doses administered to human beings seemed to be innocuous. Thus the hope emerges that it may be possible to maintain in the blood a sufficient concentration to inhibit some of the organisms of disease. The prospect is all the more alluring, as penicillin has been found to be many hundred

times as active as the sulfonamides, which marked a great advance in therapeutics. Penicillin is beginning to attract much attention, but its therapeutic use remains to be worked out. Attempts are being made to obtain the drug in a purer and crystalline form.

Pharmacists Say That Physicians Should Not Dispense Medicines

In this country general practitioners supply the medicines for the patients under their care, but only consultants write prescriptions, which are dispensed by pharmacists or by the general practitioner with whom they see the case in consultation. When the National Health Insurance Act was passed, the government decided that prescriptions should be written in official books and dispensed by pharmacists. This removed much dispensing from the sphere of the general practitioner, but he still dispenses for his private patients. Pharmacists criticize this custom, which has existed for generations and is a relic of the days of the "apothecary," who combined some knowledge of medicine with pharmacy and was the progenitor of the general practitioner. The Pharmaceutical Society of Great Britain and the National Pharmaceutical Union have submitted a joint memorandum to the Committee on Social Insurance and Allied Services on the position of pharmacy in the future health services of the country. They urge that, as in the case of national health insurance, the supply of medicines for other domiciliary treatment should be in the hands of pharmacists. They give the following reasons: 1. The training of the physician in pharmacy becomes progressively smaller as the medical curriculum widens. 2. The physician supplying his own medicines is not likely to have available the wide range of medicaments which the pharmacists serving the patients of many physicians must stock. 3. The practitioner can supply his medicines only when he is at his surgery (unless he is able to employ a dispenser), which limits the opportunity of his patients to obtain them. 4. There is no inspection of physician's dispensaries, and tests of drugs or the accuracy of the dispensing are not applicable. Finally, the memorandum urges the importance of the pharmacist as an adviser, which modern conditions have increased. The physician frequently needs information about the properties of medicinal substances and guidance in their choice and the form in which they should be prescribed. It is suggested that without this information and guidance his prescribing tends to take on a stereotyped character or to be unduly influenced by propaganda to promote the use of proprietary products. One difficulty of the proposal is not mentioned. In rural districts it may be much easier for the patient to obtain his medicines from the physician than from the pharmacist in the nearest town, which may be many miles away.

No Heat Stroke Among Desert Tank Crews

A careful analysis of the casualties incurred by the British forces during the fighting in Libya and Egypt shows, somewhat to the surprise of the medical authorities, not a single case of heat stroke or heat exhaustion among tank crews as a result of the heating of the vehicles. The explanation appears to be that the movement of the tank provides sufficient aeration to prevent a dangerous rise of temperature.

Chinese Students for Britain

It is stated that examinations are now being held in four Chinese cities for students anxious to visit Britain to take advanced courses in engineering, shipbuilding, pharmacology and economics. In the House of Commons Mr. Eden, secretary for foreign affairs, said that arrangements are now under consideration whereby Chinese students will be brought to this country for postgraduate courses under the auspices of the British universities, the British Council and the Universities' China Committee.

Fatal Mistake from Similarity of Names Procaine and Percaine

A woman dispenser in a hospital received a written slip from the theater sister asking for 1 Gm of procaine. Thinking that procaine and percaine were identical, she dispensed the latter. She used crystals from a bottle of percaine and used them to make a solution, which she labeled procaine. For a skin grafting operation a surgeon decided to use a 5 per cent solution of procaine as a local anesthetic and asked the sister for this. When the operation was finished the patient had a convulsion. Six more followed in a quarter of an hour and death occurred within three quarters of an hour after the operation. An inquest followed, at which the medical evidence was that the necropsy showed that death was due to heart failure and shock. The solution used was found to be percaine. The normal maximum dose of procaine is 2 Gm, and the surgeon had injected 1.25 Gm, a perfectly safe dose. But percaine is a different matter. It is a more powerful anesthetic and is more toxic. The safe dose for an adult is 0.12 Gm. The patient had received ten times the maximum dose and this was the cause of death. It was unfortunate, said the medical witness, that names so similar as procaine and percaine should be used.

Shortage of Rubber Gloves

The loss of the Dutch East Indies as a source of rubber has produced an extreme shortage. In view of conserving supplies for essential war requirements the Ministry of Health has found it necessary to restrict the sale of household rubber gloves to persons who are certified by physicians to be suffering from long and intractable eczema, cheiropompholyx or intractable dermatitis. Any one desiring to purchase rubber gloves for household duties can do so only if her physician certifies that she suffers from one of the three conditions mentioned and that the gloves are necessary for that purpose.

Marriages

ALBERT M. HARRIS, Little Rock, Ark., to Miss Margaret Eleanor Hofstad of Sioux Falls, S. D., August 5.

JOSEPH LAWSON PLATT, Charlottesville, Va., to Miss Louise Amonette Davis of Lynchburg, June 27.

LESLIE HOWELL HUBBARD, Montevallo, Ala., to Miss Gene Lewis of Montgomery, September 6.

CHARLES EDWARD McKEOWN, Richmond, Va., to Miss Margaret Parker of Alexandria, July 3.

PHILLIP COCKE TROUT, Roanoke, Va., to Miss Bettie Ruth Reynolds of Shawsville, July 1.

THOMAS PAUL O'BRIEN, Benwood, W. Va., to Miss Jacqueline Weeks of Crewe, July 13.

JOSEPH H. RENO, Philadelphia, to Miss Maude O. Mutchler of Blackwood, N. J., June 27.

MOSES H. McCLINTIC, Roanoke, Va., to Miss Kathryn Meador of Bedford, June 20.

GEORGE L. REGAN, Sellersburg, Ind., to Miss Betty Stephens of New Albany, June 18.

MARION R. SCHELTZ, Lewisville, Ind., to Miss Lorena Ryman of Knightstown, June 14.

COSMO JOSEPH TARDO to Miss Lena Anna Amato, both of New Orleans, August 6.

GEORGE W. JAMES, Humboldt, Tenn., to Miss Virginia Walke of Dublin, Ga., July 16.

HAROLD V. SMITH, Kearney, Neb., to Miss Florence Nellis of Hartington, July 29.

LOUIS FRIEDFELD, Brooklyn, to Miss Helen Levine of New York, August 23.

ROOSEVELT BROOKS to Miss Gwendolyn Redmon, both of Chicago, June 27.

CYNTHIA T. MORTON to Charles C. Ashley, both of Paris, Ill., July 1.

Deaths

Owing to the accumulation of material of military importance, the publication of obituaries has been somewhat delayed hence the publication of four pages in this issue

Edward Jackson, Denver professor emeritus of ophthalmology at the University of Colorado School of Medicine died October 29 of heart block, aged 86.

Dr Jackson was born in West Goshen, Pa. March 30, 1856. After graduation from the University of Pennsylvania Department of Medicine, Philadelphia in 1878, he practiced in West Chester and in Philadelphia. In 1888 he became professor of diseases of the eye at the Philadelphia Polytechnic and served in that capacity until 1894 and again from 1896 to 1898. During this period he was surgeon to the Wills Eye Hospital. Following his move to Denver, he was professor of ophthalmology at the University of Colorado School of Medicine, 1905-1921.

Dr Jackson was especially noted for his leadership in the field of ophthalmology. He was chairman of the Section on Ophthalmology of the American Medical Association in 1887-1888 and again in 1894-1895. He was president of the Western Ophthalmological Society in 1934. He was a member of the American Ophthalmological Society, the Association for Research in Ophthalmology and the Pacific Coast Oto Ophthalmological Society. In 1940 he was elected vice president of the Pan American Congress of Ophthalmology. From 1925 to 1935 he was president of the Colorado Commission for the Blind. He was also president of the American Board for Ophthalmic Examinations in 1916-1917.

In the American Medical Association Dr Jackson was first vice president in 1904-1905 and a member of the House of Delegates from 1909 to 1912. At several sessions of the Association he was nominated to receive the distinguished service medal. He had served also as president of the Colorado State Medical Society in 1917.

Dr Jackson was internationally famed for his contributions to the literature of ophthalmology. He was American editor of *Ophthalmic Review*, London, from 1890 to 1915 and editor of the *American Journal of Ophthalmology* from 1918 to 1928. He was author of 'Essentials of Diseases of the Eye' in 1890, 'Skiascopy' in 1895, 'Manual of Diseases of the Eye' in 1900 and the 'Ophthalmic Year Book' from 1904 to 1917.

The distinction of Dr Jackson was recognized by the honorary degree of doctor of science granted to him by the University of Colorado in 1927. In 1931, as a tribute from his friends, his portrait was presented to the Medical Society of the City and County of Denver. On his eighty-third birthday, in 1939, another portrait was painted for the Wills Hospital, Philadelphia.

Among ophthalmologists who have aided greatly the extension of education regarding the eye to the public and nationwide movements for the prevention of blindness, Dr Jackson's contribution is especially significant. He traveled widely in the promotion of such efforts. By his death this specialty of medicine loses one whose contribution in its advancement for more than half a century was tremendous.

Sigmund Schulz Goldwater, New York, preeminent as a hospital administrator as a consultant in hospital construction, recognized throughout the world as a leader in this field, aged 69, died October 22, in the Mount Sinai Hospital, New York, of which he was for many years superintendent.

Dr Goldwater graduated from the University and Bellevue Hospital Medical College in 1901. He entered promptly into

the specialty which was to be his life work. He became superintendent of the Mount Sinai Hospital in New York City and occupied that position from 1903 to 1916 and was director of the hospital from 1917 to 1929. During this period he served also as municipal expert in hospital construction and administration. In 1908 he was elected president of the American Hospital Association. Almost from the first he assumed civic and public health duties of the greatest importance in advancing medicine throughout the nation. He was commissioner of health of New York City from 1914 to 1918, vice president of the New York Academy of Medicine in 1913 and vice president of the National Institution of Social Sciences from 1918 to 1921 and from 1924 to 1926. He had also been president of the American Conference on Hospital Service, medical counselor of the U. S. Veterans Bureau in 1924 and consulting expert to the U. S. Public Health Service.

Dr Goldwater's eminence in his chosen field was recognized by election to honorary membership in the British Hospital Association. In 1925 he was awarded the honorary degree of doctor of science by Marquette University, Milwaukee, and in 1939 received the honorary degree of doctor of public health from New York University.

In 1940 he was selected to receive the award of merit of the American Hospital Association. In 1933 Dr Goldwater had been appointed consulting expert to collaborate with Russian architects, engineers and clinics in the planning of hospitals in Leningrad and elsewhere in the Soviet Union.

Following his retirement from active association with the Mount Sinai Hospital, Dr Goldwater served in many public capacities. From 1934 to 1940 he was commissioner of the department of hospitals of New York City and since 1941 had been vice president of the research council of that department. Since 1940 he had also been president of the Associated Hospital Service of New York City and had been especially active in developing the extension of prepayment plans. He was a trustee of the United Hospital Fund of New York and also of the Huntington (N. Y.) Hospital. At the time of the National Health Conference he had been most active in presenting the cause of the voluntary hospital. In his death medicine loses a wise counselor and a recognized leader in the advancement of medical and hospital services.

Herbert Anthony Potts, Chicago, Northwestern University Dental School in 1895 and Northwestern University Medical School in 1901, in 1908 demonstrator of operative surgery, in 1917 professor of oral surgery and since 1938 professor emeritus at the Northwestern University Medical School, lecturer on anesthesia and assistant in oral surgery from 1908 to 1913, professor of pathology, lecturer on anesthesia and assistant in oral surgery from 1913 to 1920, professor of oral surgery from 1920 to 1939 and since Sept. 1, 1939 professor emeritus at the Northwestern University Dental School, chairman of the Section on Stomatology of the American Medical Association, 1921-1922, secretary of the section 1924-1925, and member of the House of Delegates in 1924, specialist certified by the American Board of Plastic Surgery, fellow of the American College of Surgeons, served as a major in the medical corps with the American Expeditionary Forces during World War I, senior oral surgeon at St. Luke's Hospital, formerly chief oral surgeon at the Evanston (Ill.) Hospital and the Cook County Hospital, aged 69, died, October 7, of cerebral arteriosclerosis at his home in Evanston.

Amand Nicholas Ravold, St. Louis, St. Louis Medical College, 1881, at one time instructor of bacteriology at his alma mater, now known as the Washington University School of Medicine, where he had been professor of bacteriology and hygiene, an Affiliate Fellow of the American Medical Association and secretary of the Section on State Medicine, 1899-1900, president of the St. Louis Medical Society in 1926, bac-

EDWARD JACKSON, M.D., 1856-1942

terologist for the city of St. Louis from 1894 to 1903, biologist in chief, in charge of the biologic survey of the Missouri Mississippi and Illinois rivers and Lake Michigan from 1898 to 1903, served as a major in the medical corps of the U S Army during World War I, formerly associated with the U S Public Health Service instructor of urology at St. Louis Polyclinic School and Hospital from 1885 to 1887, instructor of bacteriology at the Shaw School of Botany, 1887-1888, physician at the St. Louis Infirmary, 1883-1884 in 1931 in recognition of his completion of fifty years in the practice of medicine, his friends presented a plaque of him to the St. Louis Medical Society aged 83 died, October 26 in the Barnes Hospital

Edward Robert Maloney * New York, Columbia University College of Physicians and Surgeons New York, 1896, since 1940 professor emeritus of dermatology and syphilology at the New York University College of Medicine, professor from 1938 to 1940 associate professor from 1932 to 1938 assistant professor from 1932 to 1935, clinical professor from 1926 to 1932 and instructor in dermatology from 1923 to 1926 specialist certified by the American Board of Dermatology and Syphilology, member of the American Academy of Dermatology and Syphilology, at one time joined the National Guard of New York as a captain in the medical corps, in 1915 served on the Mexican border and as a lieutenant colonel during World War I, in 1924 was made a colonel in the medical reserve corps president of the medical board of St. Vincent's Hospital and since 1921 visiting dermatologist, consultant in dermatology at the Bellevue Hospital and the New York Foundling Hospital New York, the Elizabeth A. Horton Hospital Middletown, N. Y., and the Pilgrim State Hospital Brentwood, N. Y. aged 68, died October 5, of coronary thrombosis

William Barrett Brinsmade, Bedford Hills N. Y. College of Physicians and Surgeons New York, 1892 emeritus professor of surgery and formerly instructor of practical obstetrics assistant demonstrator and demonstrator of anatomy, instructor of operative surgery, chief of the surgical clinic and clinical professor of surgery at the Long Island College of Medicine Brooklyn, surgical director of the U S Army Hospital number 202 and consulting surgeon of hospitals in Brest France during World War I was cited by Gen. John J. Pershing 'for exceptionally meritorious and conspicuous service' was decorated with the Order of the Purple Heart and was a Chevalier of the French Legion of Honor, commander in the U S Naval Reserve Corps, member of the American Surgical Association, fellow of the American College of Surgeons, aged 76, formerly consulting surgeon to the Long Island College Hospital Brooklyn, St. John's Hospital Brooklyn, and the Brooklyn Hospital, where he died, September 23, of cerebral embolism

John Hyren Peck * Oakdale, Iowa, State University of Iowa College of Medicine, 1909, specialist certified by the American Board of Internal Medicine, member of the House of Delegates of the American Medical Association in 1921, past president of the Iowa State Medical Society Polk County Medical Society and the Mississippi Valley Conference on Tuberculosis, member and past president of the American College of Chest Physicians, past president and vice president of the National Tuberculosis Association, past president of the Iowa Tuberculosis Association, fellow of the American College of Physicians, served as a major in the U S Army and as chief of the tuberculosis service during World War I lecturer on tuberculosis at his alma mater superintendent of the State Sanatorium, aged 63, died, October 18, of coronary occlusion

Walter Gresham Sexton * Marshfield, Wis. Johns Hopkins University School of Medicine Baltimore 1911, specialist certified by the American Board of Urology, Inc. member of the American Urological Association and formerly secretary, treasurer and president of the North Central Branch fellow of the American College of Surgeons at one time secretary of the Wood County Medical Society formerly member and president of the board of education, member of the county draft board and served as a lieutenant in the medical corps of the U S Army during World War I on the staffs of St. Joseph's Hospital and the Marshfield Clinic aged 56, died September 27 in the Worrell Hospital Rochester Minn., of arteriosclerosis and malignant hypertension

Frank William Marlow, Syracuse N. Y., M.R.C.S. England and L.S.A., London 1880, Syracuse University College of Medicine 1885, member of the Medical Society of the State of New York the American Ophthalmological Society and the Ophthalmological Society of the United Kingdom specialist certified by the American Board of Ophthalmology, fellow of the American College of Surgeons professor emeritus

of ophthalmology at his alma mater, where he was formerly instructor, lecturer and professor of ophthalmology and otology, for many years on the staffs of the Syracuse Memorial Hospital, St. Joseph's Hospital, Hospital of the Good Shepherd and the Syracuse Free Dispensary, aged 84, died, October 4

Maxillian A. Bussewitz, Milwaukee, Wisconsin College of Physicians and Surgeons Milwaukee, 1907, member of the State Medical Society of Wisconsin, professor emeritus of physiology at the State Teachers College, Milwaukee, formerly professor of physiology at Marquette University, assistant state superintendent of public instruction, 1901-1902, secretary of the Wisconsin State Teachers' Association from 1910 to 1922 lieutenant colonel in the medical officers' reserve corps and served in the Wisconsin National Guard from 1892 to 1894, formerly teacher in physiology at the Trinity Hospital and St. Mary's Hospital, where he died, September 20, aged 75

Robert James Lawler * Surgeon, Lieutenant Commander, U S Navy retired, Elmira, N. Y., University of Buffalo School of Medicine, 1904, entered the medical corps of the U S Navy in 1921 and retired in 1930 for incapacity resulting from an incident of service, served during World War I, for outstanding service received the Navy Cross the Distinguished Service Cross the Honorary Badge of Military Merit of the Purple Heart and the Croix de Guerre, senior medical officer of the Buffalo recruiting district of the U S Marine corps, aged 59 died October 1, in St. Joseph's Hospital of myocarditis

James Givens Carpenter, Lebanon, Ky., University of the City of New York Medical Department, 1875, member and past president of the Kentucky State Medical Association, past president of the Central Kentucky Medical Society, formerly U S examining surgeon for pensions, at one time chairman of the board of health and health officer of Lincoln County, formerly physician in charge of the Joseph Price Infirmary, Stanford, at one time lecturer on gynecology at the Barnes Medical College, St. Louis, aged 88, died, October 7, in Louisville

Gilbert Tyson Smith, McDaniel, Md., University of Maryland School of Medicine, Baltimore, 1897, served as assistant physician at the Logansport (Ind.) State Hospital from July 5 to Sept. 5, 1942 formerly assistant superintendent of the Yankton (S. D.) State Hospital the Mansfield State Training School and Hospital, Mansfield Depot, Conn. and the Huntington (W. Va.) State Hospital, at one time chief surgeon of several steamships of the United American Lines, Inc., of New York aged 68, died September 22, in Laurel

Robert White Knox, Houston, Texas, University of Virginia Department of Medicine, Charlottesville 1882 member and past president of the State Medical Association of Texas member of the House of Delegates of the American Medical Association, 1904-1905 in 1908 and 1927-1928, fellow of the American College of Surgeons for many years chief surgeon of the Southern Pacific Hospital, member of the board of the Hermann Hospital, aged 82, died, September 27, of coronary thrombosis

Ned Overton Lewis * Major, U S Army, retired Rancho Santa Fe Calif., University Medical College of Kansas City Mo., 1905 entered the medical corps of the U S Army as a major in 1920 retired Nov. 30, 1933 for disability in line of duty, served during World War I, at one time demonstrator of anatomy at his alma mater formerly assistant police surgeon in Kansas City, Mo., aged 60 died, August 31, of coronary thrombosis

Charles Robert Sowder, New Castle Ind. Central College of Physicians and Surgeons Indianapolis 1898 clinical professor of medicine at the Indiana University School of Medicine, member of the Indiana State Medical Association served in the medical corps of the U S Army during World War I formerly visiting physician to the Indianapolis City Hospital, aged 72 died September 29 in Indianapolis

Littleberry Starback Foster, Williamsburg Va. University of the City of New York Medical Department, 1879 member of the Medical Society of Virginia formerly super-

intendent of Matthews County schools, member of the state board of education and the state board of medical examiners, at one time director and superintendent of the Eastern State Hospital, aged 80, died, September 23

Elmer Grant Weibel ♂ Eric, Pa., University and Bellevue Hospital Medical College, New York, 1899, member of the Radiological Society of North America, Inc., past president of the Erie County Medical Society, served for three years in the medical corps of the regular U S Army and during World War I on the consultant staff of the Hiram and St Vincent's hospitals, aged 71, died, September 19

David J Levy ♂ Detroit, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1906, specialist certified by the American Board of Pediatrics, Inc., member of the American Academy of Pediatrics, at one time health officer of Kalamazoo Mich. formerly on the staffs of the Herman Kiefer Hospital, the Woman's Hospital and the Harper Hospital, aged 61, died, October 14

Frank James Hackett, Westmount, Que., Canada, University of Bishop College Faculty of Medicine, Montreal, 1892, a founder and for many years secretary of the medical board of the Western Hospital, Montreal, when it became the Western Division of the Montreal General Hospital he served on the consulting staff, on the staff of St Mary's Hospital, Montreal, aged 79, died, September 7

Robert S Curry, Jackson, Miss., Medical College of Alabama, Mobile, 1885, past president of the Mississippi State Medical Association, served as state factory inspector for the state board of health from 1924 to 1929, formerly a member of the House of Representatives from Ifinds County, for eight years superintendent of the Mississippi School for the Blind, aged 80 died August 20

Joseph Arkell Campbell ♂ Marissa, Ill., St Louis University School of Medicine 1906 formerly managing officer of the East Moline (Ill) State Hospital and the Anna (Ill) State Hospital, served as a major in the medical corps of the U S Army during World War I, aged 60, died, October 6, in the Barnes Hospital, St Louis, following an operation for brain tumor

Mary Louise Lines, Brooklyn, University of Michigan Homeopathic Medical School, Ann Arbor, 1884, member of the Medical Society of the State of New York, specialist certified by the American Board of Ophthalmology, consultant electrotherapist, Brooklyn Eye, Ear, Nose and Throat Hospital, aged 83, died, October 5, of coronary disease at Stonybrook

Sydney Algernon Dunham, Buffalo, Niagara University Medical Department, Buffalo, 1888 at one time lecturer of physiology at his alma mater, member of the Medical Society of the State of New York, formerly served as Erie County postmortem examiner, for many years owner of the Parlside Sanitarium and Hospital, aged 83, died, September 22

Willard Phipard, New York, University of Vermont College of Medicine, Burlington, 1913, served as a lieutenant in the medical corps of the U S Army during World War I, a member of the medical board and an attending surgeon on the staff of the Lutheran Hospital, aged 55, died, October 6, of acute hemorrhagic pancreatitis and toxic hepatitis

Harry Duffield Clough, Rochester, N Y, Johns Hopkins University School of Medicine, Baltimore, 1915, assistant medical director of the Rochester General Hospital for many years secretary of the Rochester Academy of Medicine, formerly assistant professor of vital economics at the University of Rochester, aged 56, died, October 1

Moses Scholtz, Arcadia, Calif., University of Moscow Faculty of Medicine, Russia, 1900, specialist certified by the American Board of Dermatology and Syphilology, professor emeritus of clinical dermatology and syphilology at the College of Medical Evangelists, Los Angeles, aged 67, died, August 29, of coronary thrombosis

Michael Charles Albi, Trinidad, Colo., Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1921 member of the Colorado State Medical Society, served with the Italian Army during World War I aged 45, died, September 29, in the Colorado General Hospital at Denver of cholema and cirrhosis of the liver

Francis Joseph Kelly ♂ Philadelphia, Jefferson Medical College of Philadelphia, 1894, served as a major in the medical corps of the U S Army during World War I, on the consultant staff of St Agnes, St Vincent's and the Misericordia hospitals, formerly on the staff of St Mary's Hospital, aged 70, died, September 3

Franklin Lyman Lawton, Hartford, Conn., Yale University School of Medicine, New Haven, 1893, member of the Connecticut State Medical Society, served as a captain in the medical corps of the U S Army during World War I, aged 72, died, September 30, in the New Haven (Conn) Hospital, of coronary occlusion

L Gibbons Smart, Towson, Md., College of Physicians and Surgeons, Baltimore, 1885, member of the Medical and Surgical Faculty of Maryland, at one time medical superintendent of the Creighton Sanitarium at Lutherville and the Rosewood State Training School at Owings Mills, aged 80, died, September 1

Clyde Vernon Powell, Forrest City, Ark., Memphis (Tenn) Hospital Medical College, 1913, member of the Arkansas Medical Society, served during World War I, health officer of St Francis County, formerly associated with the Indian Service, aged 54, was killed in an automobile accident, August 13

Henry Garrison Camp, Jasper Ala., Birmingham Medical College, 1915, member of the Medical Association of the State of Alabama, formerly chief medical advisory officer of the department of correction and institutions of the state of Alabama, aged 63, died, September 30, of Hodgkin's disease

Louis Cotten Skinner, Greenville, N C., University of Maryland School of Medicine, Baltimore 1901, member of the Medical Society of the State of North Carolina, past president of the Pitt County Medical Society, aged 62 died, September 20, in the Union Memorial Hospital, Baltimore

James Charles Egan, Chicago, Keokuk (Iowa) Medical College, 1894, member of the Illinois State Medical Society, at one time professor of proctology at the Illinois Medical College, aged 78, on the staff of the Edgewater Hospital, where he died, October 10, of cerebral hemorrhage

John King Evans, Malvern, Pa., Bellevue Hospital Medical College, New York, 1884, member of the Medical Society of the State of Pennsylvania, past president of the Chester County Medical Society, past president of the school board of Malvern, aged 82, died, October 3, of arteriosclerosis

Daniel Francis White, Buffalo, Niagara University Medical Department, Buffalo 1893, member of the staffs of the Emergency Hospital of the Sisters of Charity and of the Millard Fillmore Hospital, aged 68, died, August 28, of arteriosclerosis and gangrene of the right foot

John Curtis Snow, Providence, Ky., University of Louisville Medical Department, 1909, served as a first lieutenant in the medical corps of the U S Army during World War I, formerly mayor of Providence and member of the board of education, aged 59, died, September 28

Walter Scott Dotson Jr ♂ Westmoreland Tenn., University of Tennessee College of Medicine, Memphis, 1934, was appointed a first lieutenant in the medical reserve corps of the U S Army Nov 21, 1939 and resigned his commission April 14, 1941, aged 34, died, September 26

Aaron Kurtzman ♂ New York, Universität Bern Medizinische Fakultät Switzerland, 1923 member of the staff of the New York Post-Graduate Medical School and Hospital, an examining physician at the Governors Island army recruiting station, aged 53, died, September 30

Wenzel August Medlin, Cleveland, Western Reserve University Medical Department Cleveland, 1900, member of the Ohio State Medical Association served during World War I, on the staff of the Lutheran Hospital, aged 65, died, September 18, of chronic myocarditis

Wilfred Davy Smith, Toronto Ont., Canada, University of Toronto Faculty of Medicine, 1911, commissioner of the Workmen's Compensation Board, at one time superintendent of the Ontario Hospital St Thomas, aged 61, died suddenly September 16, in St John N B

James Michael Bernhard, Amsterdam N Y, Albany Medical College 1917, member of the Medical Society of the State of New York served during World War I, aged 50 on the staff of St Mary's Hospital, where he died, September 25 of coronary thrombosis

Abram Robert Goodman, Chaumont, N Y, University of Oklahoma School of Medicine, Oklahoma City 1917, member of the Medical Society of the State of New York served as a lieutenant in the medical corps during World War I, aged 48, died, August 18

Robert Lucas Pitfield, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1892, for many years on the staff of the Germantown Dispensary and Hospital author of 'Compend on Bacteriology', aged 72, died, October 3 of coronary disease

Eugene Gagnon, Montreal, Que. Canada. School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1902, demographer and statistician to the health department of Montreal, aged 65, died, September 3.

Oswald Felix Schiffli, Clewiston, Fla., Chicago College of Medicine and Surgery, 1917, member of the Florida Medical Association, served during World War I and as a captain in the medical corps of the regular army, aged 51, died suddenly, August 18.

George Waller Dawson, Dalhart, Texas. Kentucky School of Medicine, Louisville, 1894, member of the State Medical Association of Texas, served as a captain in the medical corps of the U. S. Army during World War I, aged 71, died, September 29.

Harry Lycan, Vernon, Ill., Marion-Sims College of Medicine, St. Louis, 1899, member of the Illinois State Medical Society, served as Edgar County coroner, aged 69, died, September 27, in Paris (Ill.) Hospital of coronary occlusion.

Samuel L. Caldwell, Colorado Springs, Colo., University of Pennsylvania Department of Medicine, Philadelphia, 1882, formerly member of the city health department, aged 89, died, September 2, in the Queen's Hospital, Honolulu, Hawaii.

Charles Horace Bradley, Groveton, Texas. Medical Department of Tulane University, New Orleans, 1906, for many years president of the Trinity County Medical Society, aged 64, died, October 12, of diabetes mellitus.

William Granville Catlin, Norristown, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1921, on the courtesy staff of the Montgomery Hospital, aged 51, died, September 26, of chronic myocarditis and nephritis.

Charles Paul Reed, Indiana, Pa., Western Pennsylvania Medical College, Pittsburgh, 1907, fellow of the American College of Surgeons, on the staff of the Indiana Hospital, aged 65, died, September 20, of angina pectoris.

Charles E. Scharnagel, Tuscaloosa, Ala., Vanderbilt University School of Medicine, Nashville, Tenn., 1896, aged 77, died, August 30, in the Norwood Infirmary, Birmingham, of uremia secondary to carcinoma of the prostate.

William LeRoy Donnelly, Davenport, Iowa, State University of Iowa College of Medicine, Iowa City, 1919, aged 49, on the staffs of St. Luke's Hospital and the Mercy Hospital, where he died, October 13.

Gottfried Metzler Sr., Ambler, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1891, on the staff of the Lankenau Hospital, Philadelphia, aged 89, died, October 1, of coronary thrombosis.

Hugh Farrior McLaurine, Midway, Ala., Vanderbilt University School of Medicine, Nashville, Tenn., 1911, member of the Medical Association of the State of Alabama, aged 54, was found dead, September 29.

Robert Edward Talley, Trion, Ga., Atlanta Medical College, 1895, member of the Medical Association of Georgia, on the staff of the Riegel Hospital, aged 72, died, September 17, of coronary thrombosis.

John H. Duncan, Millport, Ala., University of Nashville (Tenn.) Medical Department, 1886, Vanderbilt University School of Medicine, Nashville, 1886, aged 80, died, September 17, in a hospital at Fayette.

Edwin Willis Twyman, Twymans Mill, Va. (licensed in Virginia by years of practice), member of the Medical Society of Virginia, formerly member of the county board of health, aged 88, died, September 15.

Walter Leon Ellis, Vashon, Wash., St. Louis College of Physicians and Surgeons, 1897, served in France as a captain in the medical corps of the U. S. Army during World War I, aged 67, died, September 28.

Earl Campbell Douglass, Fort Lauderdale, Fla., Medico-Chirurgical College of Philadelphia, 1904, served as a major in the medical corps of the U. S. Army during World War I, aged 62, died, September 29.

John Walter Dickinson, Oscoda, Mich., Marion-Sims College of Medicine, St. Louis, 1898, member of the Michigan State Medical Society, owner of a hospital bearing his name, aged 68, died, September 11.

John Robert Tinsley, Middlesboro, Ky., Hospital College of Medicine, Louisville, 1907, member of the Kentucky State Medical Association, past president of the local school board, aged 58, died, September 18.

Aaron John Bond, Adams, Mass., New York Homeopathic Medical College, New York, 1883, for many years a member

of the school committee and of the board of health, aged 85, died, August 31, of senility.

Ignac Neumann, New York, University of Vermont College of Medicine, Burlington, 1892, consulting physician on the staff of the Hospital for Joint Diseases, aged 78, died, October 1, of prostatic obstruction.

William Frederick Myers, Coal Valley, Ill., Kentucky School of Medicine, Louisville, 1892, Hospital College of Medicine, Louisville, Ky., 1893, aged 74, died, October 9, of carcinoma of the stomach.

Thomas H. Keeley, Monson, Mass., Middlesex College of Medicine and Surgery, Cambridge, 1923, on the staff of the Wing Memorial Hospital, Palmer, aged 48, died, August 28, of bronchopneumonia.

William Bennett Palamontain, Oakland, Calif., Cooper Medical College, San Francisco, 1904, aged 66, died, September 18, in Houston, Texas, of hemiplegia, uremia and hypostatic pneumonia.

Raymond William Durkee, Des Moines, Iowa, Rush Medical College, Chicago, 1895, aged 71, died, September 29, in the Broadlawn Polk County Public Hospital of uremia and chronic nephritis.

Clair Wilson, Los Angeles, College of Physicians and Surgeons, Los Angeles, 1917, served during World War I, aged 49, was found dead in bed, September 6, of coronary thrombosis.

John William Joyce, New York, Medical School of Maine, Portland, 1898, for many years on the staffs of the Misericordia and St. Bartholomew's hospitals, aged 67, died, September 4.

Clem Stewart Campbell, South Bend, Ind., University of Louisville (Ky.) Medical Department, 1908, member of the Indiana State Medical Association, aged 59, died, September 30.

Charles William Green, Selkirk, Man. Canada, Manitoba Medical College, Winnipeg, 1909, aged 71, died, September 23, in the Hospital for Mental Diseases of coronary thrombosis.

James A. Smith, Lyerly, Ga., University of Louisville (Ky.) Medical Department, 1880, member of the Medical Association of Georgia, aged 85, died, August 17.

John Henry Becker, Palm Springs, Calif., College of Medical Evangelists, Los Angeles, 1925, aged 42, died, August 29, of arteriosclerotic heart disease.

Lincoln Bond Griswold, Utica, Ill., Loyola University School of Medicine, Chicago, 1923, aged 46, died, September 30, of lymphocarcinoma.

Sam P. Ford, Parkville, Mo., Physio-Medical College of Indiana, Indianapolis, 1900, aged 72, died, August 25, of coronary disease.

R. T. Strange, Fort Smith, Ark. (licensed in Arkansas in 1903), aged 70, died, October 1, of pulmonary tuberculosis.

John Harold Cook, Terre Haute, Ind., Miami Medical College, Cincinnati, 1906, aged 61, died, September 5.

George H. Hess, Philadelphia, College of Physicians and Surgeons, Baltimore, 1897, died, September 2.

Erfield B. Berry, Chicago, National Medical University, Chicago, 1899, aged 64, died, September 18.

John Goethals, Brooklyn, United States Medical College, New York, 1880, aged 86, died, August 24.

DIED WHILE IN MILITARY SERVICE

George Clayton Wassell, Pittsburgh, St. Louis University School of Medicine, 1935, U. S. Army School of Aviation Medicine, Randolph Field, Texas, 1942, on the staff of the Christian H. Buhl Memorial Hospital, Sharon, Pa., called to active service as a first lieutenant in the medical reserve corps of the U. S. Army April 1, 1941, appointed a captain June 1, 1941, assigned to U. S. Bomber Command, as flight surgeon for overseas duty September 1942, aged 32, was killed in an airplane accident over the British Isles, October 3.

Raymond Cunningham Stiles, Captain M. C. U. S. Army, Kansas City, Kan., Baylor University College of Medicine, Dallas, Texas, 1937, entered the medical corps of the U. S. Army as a first lieutenant in 1939, was appointed a captain in 1942, aged 30, was killed in an airplane accident about 30 miles from Ponce, Puerto Rico, October 1.

Venus Tablets—Thoro Sales Service Los Angeles Shipped between May 6 and Sept 22 1940 Composition rhubarb root kelp, Irish moss and green leafy material accompanying specimen of V 76 Lavative Tablets contained dry rhubarb root cranberries and green leafy material Venus Tablets misbranded because label falsely implied that the product would help control body weight enable the user to attain an ideal and slender form lose ugly fat and feel and look better Misbranding also charged against Venus Tablets and V 76 Lavative Tablets because labels did not properly warn against their use by children or against unsafe dosage or duration of taking them—[D D N J F D C 343 March 1942]

PATHOLOGIC RENAL CHANGES

To the Editor—In the excellent and clear article concerning pathologic renal changes by Dr J P Simonds in *THE JOURNAL*, September 12, are two points concerning which I would appreciate further enlightenment

1 Dr Simonds states that because of water loss from the blood in its passage through the glomeruli the osmotic pressure of the plasma proteins in the peritubular capillaries is higher than elsewhere and that the hydrostatic pressure of the blood in these capillaries is lower than the osmotic pressure, he then states that water and solutes withdrawn by tubular reabsorption from the glomerular filtrate into the surrounding tissue spaces are quickly drawn into the peritubular capillaries by the increased osmotic pressure of the plasma proteins of the blood in these vessels" Admitting the first statement, I believe it requires some explanation for the second statement that solutes as well as water are drawn into capillaries because of the increased osmotic pressure of their contents, the drawing in of water goes without saying, but the drawing in of solutes would further increase the osmotic pressure and does not seem evident

2 Dr Simonds states that metallic poisons such as mercury bichloride are filtered out through the glomeruli and not reabsorbed by the tubular epithelium but that they are concentrated in the tubular lumens by the absorption of water and in this way damage the proximal convoluted tubules Is it not possible that such poisons damage tubular epithelium because they are excreted by those epithelial cells and are therefore concentrated there? How else does one explain that mercury and uranium affect especially the distal parts of the proximal convoluted tubules whereas chromium affects especially the proximal and middle parts of the convoluted tubules? Why should they not all affect the same portions if they are excreted by the glomeruli and cause their damage simply by their concentration due to absorption of water? This selectivity suggests that they are excreted by different portions of the tubules

ERNEST B ZEISLER M D, Chicago

[The letter was referred to Dr J P Simonds, who replies]

To the Editor—In answering the first question in the letter of Dr Zeisler a distinction must be made between the total osmotic pressure of the plasma and that part of the total which is effective in controlling the exchange of fluids between blood and tissues The solutes in the plasma are responsible for the greater part of its total osmotic pressure but, because the walls of the capillaries are permeable to them, they have little or nothing to do with the exchange of fluids between blood and tissue spaces For the latter, the osmotic pressure of the plasma proteins and the hydrostatic pressure of the blood in the capillaries are responsible The drawing of solutes into capillary blood will obviously increase the total osmotic pressure of the plasma but will not alter the effective osmotic pressure of the plasma proteins The latter will be reduced by the drawing in of water as a result of dilution

The physicochemical conditions in the system composed of the blood in the peritubular capillaries and the fluid in the peritubular spaces are similar in all essential respects to those in Donnan's equilibrium, in which crystalloids pass through a semi-permeable membrane In Donnan's experiment time is required for equilibrium to become established between the solution containing colloid and crystalloid on one side, and that containing crystalloid only on the other side, of the membrane This type of equilibrium between the blood in the peritubular capillaries and the surrounding tissue fluids (water and solutes) is therefore never complete because the plasma in the peritubular capil-

laries is being continually changed by the flow of blood In this manner there is maintained a constant physicochemical condition favorable to the rapid and continuous passage of water and solutes from the tissue spaces into the peritubular capillaries

2 The view that such poisons as the salts of mercury and uranium and of chromic acid are excreted by the tubular epithelium has certain attractions but also serious difficulties Not the least of these difficulties is the fact that excretion of any substance by the tubules of the mammalian kidney must take place against the very high osmotic pressure of the concentrated plasma proteins in the peritubular capillaries It is only the proteins of the plasma that are concentrated in these vessels

The tubules of the aglomerular kidneys of certain fish are capable of excreting water and all the other constituents of urine This normal function in these animals is not performed against an osmotic pressure of plasma proteins in peritubular blood which has been augmented by glomerular filtration, as in the mammalian kidney The tubules of the human kidney, on the other hand, are not known to excrete any of the normal endogenous constituents of the urine All the crystalloidal substances in the urine are excreted by glomerular filtration The three poisons mentioned are crystalloids It is a natural supposition, but not necessarily an established fact, that they are also excreted by the glomeruli The tubules of the mammalian kidney can, however, excrete certain extraneous substances, such as phenolsulfonphthalein, diodrast and even exogenous creatinine. That is, excretion by the tubules is a potential function and it cannot be categorically denied that they may excrete the crystalloidal poisons mentioned Phenolsulfonphthalein, diodrast and exogenous creatinine, all essentially nontoxic to the kidneys, are excreted both by glomerular filtration and by tubular excretion It is not impossible, therefore, that these crystalloidal poisons may also be excreted by both mechanisms While the possibility of a dual type of excretion is admitted, it does not appear likely that these poisons are excreted solely by the tubules, as is implied in the foregoing letter

The selective effect of these poisons on specific portions of the proximal convoluted tubules is not an insurmountable difficulty in accepting the view that they are excreted only by glomerular filtration Variations in susceptibility of the epithelium in different parts of the renal units are known to exist Any nonabsorbable poison in the glomerular filtrate attains its greatest concentration in Henle's loop, and yet the epithelium of this portion of the nephrons and that of the distal convoluted tubules show little evidence of damage by the poisons under consideration There is also a difference in degree of toxicity of these three substances For example, it was found that 3 mg of mercury bichloride per hundred cubic centimeters of circulating blood given intravenously will kill a dog in five days or less, while 3 mg of potassium dichromate or of uranyl nitrate in the same proportion were not fatal

In unpublished experiments designed to determine the minimal amount of these poisons that will produce visible damage to the tubular epithelium after intravenous injection their selective action on the epithelium at different levels of the proximal convoluted tubules was substantially confirmed Presumably, the chromium, mercury and uranium are the toxic elements in their respective molecules One mg of potassium dichromate (K_2CrO_4) contains 6.79×10^{-3} gram atoms of chromium, 1 mg of mercury bichloride ($HgCl_2$) contains 3.69×10^{-3} gram atoms of mercury and 1 mg of uranium (uranyl) nitrate [$UO(NO_3)_2$] contains 1.995×10^{-3} gram atoms of uranium If absorption is continuous and progresses at essentially the same rate throughout the whole course of the proximal convoluted tubule, it is evident that there would be a greater concentration of chromium atoms at a higher level in these tubules than of either mercury or uranium This may account for the visible effects of potassium dichromate in the first third of the proximal convoluted tubules

J P SIMONDS M D, Chicago

IRRADIATED ERGOSTEROL POISONING

To the Editor—Your issue of May 16 has reached me somewhat belatedly, for reasons that need not be elaborated. I note therein a report by Lumilly and Howard on 2 cases of irradiated ergosterol poisoning. It is made quite clear in the text of the paper that the patients were fed mixtures of calciferol, lumisterol, tachysterol and toxisterol, and I cannot see any reason for attributing the intoxication to calciferol rather than to one or other of the nonantirachitic substances. It is perhaps significant that in this country, where irradiated ergosterol went out of use over ten years ago and was entirely replaced by preparations of pure calciferol, there have been no reports of intoxication, though this may have been due to the conservative dosage adopted by the majority of practitioners in this country. Moreover, tachysterol and toxisterol, and possibly one or both of the suprasterols, have a toxic action and little, if any, antirachitic effect, with crude irradiated ergosterol mixtures, therefore, any toxic effect may well be due entirely to one or other of these compounds and not to vitamin D at all. Although calciferol itself is probably toxic in very large doses, I suggest that one must treat with considerable skepticism all reports of 'hypervitaminosis D' in human subjects that had not received pure calciferol as the sole antirachitic agent.

May I also suggest that the authors of the paper in question have been unfortunate in referring frequently therein to "ergosterol poisoning"? Ergosterol itself is as far as we know, a completely inert substance physiologically, and it would be a pity if, by casual reading, any one should gain the impression from their article that it is possible to produce toxic effects with it. The phrase 'irradiated ergosterol poisoning' is not open to this criticism but is subject to another, namely that it refers to a mixture of several substances and that we seldom, if ever, know the proportions in which they are present or the extent to which each may be responsible for any toxic effects.

A L BACHMANN, M A, F I C, Middlessex, England

ARTIFICIAL INSEMINATION

To the Editor—In the interesting article by Dr Alan F Guttmacher on artificial insemination on page 442 of THE JOURNAL for October 10 there is a serious omission. The author cites certain indications for artificial insemination among which are impotence, hypospadias in the male, and some pathologic conditions in the female. He omits to state, however, that the Huhner test should be made in all of these conditions before resorting to artificial insemination. I have seen many cases both in male and female in which there were all sorts of pathologic conditions and still the Huhner test disclosed live spermatozoa on and within the cervix, showing that the pathologic condition did not interfere with the deposit of the spermatozoa. It is not at all unusual for impotent patients to impregnate their wives. This is the chief advantage of the Huhner test in the diagnosis of sterility. If I find spermatozoa within the cervix, I do not care what pathologic conditions are found for I know that the male is able to deposit his semen in the right place.

In discussing aspiration of the testicles and injecting the aspirated testicular fluid into the female cervix, I was the first to try this procedure and reported several attempts on pages 103, 104, and 105 in my book "Sterility in the Male and Female" published in 1913. All my attempts were failures, but Kenneth M Walker on page 177 in his book "Male Disorders of Sex" published in London in 1930 gives a successful case by Mr C H Mills, an English surgeon.

MAX HUHNER, M D, New York

IN DEFENSE OF PHYSICAL THERAPY

To the Editor—Although Sister Kenny's concept of treating poliomyelitis in the acute stage had a purely empiric origin, her observations were so acute that they approached truth, as truth is revealed in nature. The rationale of her physical therapeutic methods is finding accruing support as the newer knowledge of the pathologic physiology of this disease unfolds.

The five papers in THE JOURNAL which were originally read in the Panel Discussion on Poliomyelitis at the Ninety-Third Annual Session of the American Medical Association enable the reader to contrast and weigh the contributions of the science of medicine, and the art of its practice, to the treatment of a single important disease. Having read these papers, one feels that, although physical therapy is a tool admittedly replete with dogma, it is neither just nor fair to blame the technical assistant for the poor results of a treatment prescribed by the doctor.

"The lack of knowledge among physicians of what physical therapy means is not their fault," writes Ober (THE JOURNAL, October 17, p 514). Who shall take the blame for this ignorance?

F A HILLEBRANDT, M D, Madison, Wis

CHEST INJURY AND CORONARY OCCLUSIONS

To the Editor—In the October 3 issue of THE JOURNAL, in a communication on chest injury and coronary occlusion (p 392), Master suggested that the use of acute coronary thrombosis in the title of my paper (Leinoff, H D, Acute Coronary Thrombosis in Industry, *Arch Int Med* 70 33 [July] 1942) was misleading. This is untrue since I definitely have suggested that in all these cases a better diagnostic term would have been acute traumatic heart disease with myocardial and pericardial damage. The conclusion also stresses the importance of a differential diagnosis between acute occlusion and traumatic heart damage.

He has further confused this subject by attempting to discuss physical exertions and direct nonpenetrating chest injuries as one. I should like to take this opportunity of stressing the fact that these two types of injuries should be considered separately at all times, since the mechanisms and the end results are entirely different.

IMPROPER USE OF THE WORD ETIOLOGY

To the Editor—One of the commonest errors in medical writing is in use of the word etiology. The precise meaning of this word, derived from the Greek words *aitia* and *logos*, is the science or study of causation. It is therefore incorrect to say the "etiology of the disease is unknown." Authors who make this common error intend to say that the cause of the disease is unknown and not that the science or study of causation is unknown.

Similar mistakes are often made with other words ending in "logy." There is no excuse for the outrageous expression "there was no pathology," as the author who writes in this manner would not dream of saying 'there was no ophthalmology' in place of stating that he found no abnormal changes in the eyes. Perhaps the worst example of medical jargon is the expression "the patient has a negative serology." Some even speak of "negative serologies."

South Dakota July Report

The South Dakota Board of Medical Examiners reports the written examination for medical licensure held at Pierre July 21-22 1942 The examination covered 13 subjects and included 100 questions An average of 75 per cent was required to pass Two candidates were examined and passed Two physicians were licensed to practice medicine by reciprocity and 1 physician so licensed on endorsement of credentials of the National Board of Medical Examiners The following schools were represented

School	PASSED	Year Grad	Number Passed
Columbia University College of Physicians and Surgeons	(1932)		1
Temple University School of Medicine	(1941)		1

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Rush Medical College	(1938)	Washington	
McGill University Faculty of Medicine	(1937)	Minnesota	

School	LICENSED BY ENDORSEMENT	Year Grad
American University of Beirut School of Medicine	(1934)	

Oregon Reciprocity Report

The Oregon State Board of Medical Examiners reports 10 physicians licensed to practice medicine by reciprocity and 3 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners on July 24 The following schools were represented

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
College of Medical Evangelists	(1941)	Washington	
Rush Medical College	(1924)	Illinois	
University of Louisville School of Medicine	(1940)	Kentucky	
Harvard Medical School	(1937)	Pennsylvania	
Washington University School of Medicine	(1939)	Missouri	
University of Nebraska College of Medicine	(1930)	Nebraska	
University of Oregon Medical School	(1939)	California

University of Oregon Medical School	(1938)	(1939)
Licensed to practice surgery only		

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts Suspension of License for Fraud and Deceit, Use of Secret Cancer Formula—The Board of Regents of the University of New York suspended for one year the license of the petitioner, a physician on the grounds (1) that he had been guilty of fraud and deceit in the practice of medicine and (2) that he had undertaken to cure or treat a disease by a secret formula The petitioner appealed to the supreme court, appellate division, third department, which reversed the disciplinary order, and the Board of Regents and the medical committee on grievances then appealed to the Court of Appeals of New York

The patient in this case was suffering from a cancerous growth on the side of her face and neck for which she was receiving treatment at Queens General Hospital She had been placed on the critical list and, in August 1938, was discharged as beyond cure with but a few weeks to live She was advised to continue radiation therapy at the clinic, however, and she did so No benefit resulted from this treatment The patient was impecunious and some time in September or early October an interviewer at the hospital told her that he knew a man who could positively cure cancer Thereafter the patient was taken to one Blalaney, apparently the discoverer of the salve which was later used He exhibited photographs of cures he claimed to have effected on others and made various representations concerning the efficacy of his treatment He explained that he was not a physician and refused personally to remove the patient's bandages or to undertake any treatment Arrangements were eventually made for the medical services to be rendered by the petitioner, who for some years had known the formula for the salve, was familiar with all its ingredients and had previously used it on healthy skin with no ill results For ten days thereafter the salve was applied to the diseased tissues, at first once every three hours and later once every four hours After ten days olive oil was applied until January 1939, when the treatment was completed At the time of the preliminary investigation of the case before the subcommittee of the grievance committee, the petitioner disclosed to the committee the ingredients of the salve and the details of his use of it and later he divulged the formula, when requested, and furnished a detailed description of treatment to the full committee

However much latitude there may be in the handling and in the decisions of cases committed to other administrative tribunals, said the Court of Appeals, the education law provides that the Committee on Grievances need not be bound by the laws of evidence in the conduct of its proceedings, but its determinations must be founded on sufficient legal evidence to sustain them Hearsay evidence alone does not meet the test, the evidence must be of a probative character In this case, said the court there was no evidence that the petitioner practiced fraud and deceit, that charge was therefore abandoned on appeal Reliance was placed only on the second charge, namely that the petitioner offered undertook or agreed to cure or treat disease by a secret method procedure treatment or medicine or that he treated operated and prescribed for a human condition by a method, means or procedure which he refused to divulge on demand to the committee on grievances The commonly accepted and understood meaning of what is secret, said the court, is that which is intentionally undisclosed or, as Webster puts it 'Something studiously concealed, a thing kept from general knowledge, what is not or is not to be revealed' The noun 'secret' is similarly defined in the Century Dictionary When used in a penal law, the word 'secret' means studiously concealed In law, a 'secret' is something 'kept from the knowledge or notice of persons liable to be affected by the act, transaction deed or other thing spoken of' It is something intentionally and studiously concealed The Court of Appeals then said that within the commonly accepted meaning of the term 'secret' and as used in the statute under consideration, it could find no sufficient legal evidence in the case that the petitioner offered undertook or agreed to cure or treat the patient

by any secret method, procedure, treatment or medicine. There was nothing secret about the medicine used or the method, treatment or procedure adopted. Neither did the petitioner studiously conceal the method, procedure or treatment which he adopted or the medicine which he used. The mere fact that the details of the formula were not known to the patient or to some other particular person did not make it secret.

There was affirmative and uncontradicted evidence that the petitioner had proposed to disclose to the medical society both the formula and the treatment it it had merit and that he divulged on demand to the committee on grievances the method, procedure and treatment adopted and used by him. The attempt to help the patient by treatment outside of electrotherapy, the court said, was known to and approved by physicians connected with the hospital in whose clinic she was under treatment. The evidence was conclusive that the petitioner made no promise or representation that the treatment would cure the patient. Even had he done so, in the absence of fraud and deceit, it would have been merely an expression of opinion and he would have committed no offense under the statute. If Blakeney at any time made any such representation, it was not made in the presence of the petitioner or with his knowledge. By every test set by the legislature concluded the Court of Appeals the petitioner committed no act condemned by the statute for which discipline could be imposed. The judgment appealed from was therefore affirmed—*Stamm v. Board of Regents of University of State of New York*, 9 A. L. (2d) 913 (N. Y., 1942).

Evidence Admissibility of Result of Lie Detector Test—The defendant was convicted of the crime of manslaughter and subsequently appealed to the Supreme Court of Michigan. Prior to the trial he submitted himself to a lie detector test the result of which, on the objection of the prosecuting attorney, was not submitted to the jury. On appeal, the defendant urged that the trial court erred in refusing to allow the results of the test to be admitted in evidence.

The Supreme Court said that the general principle of the acceptance of the lie detector test is set forth in 20 Am. Jur. p. 633 as follows: "Physiological or psychological deception tests used as instruments for the ascertainment of the truthfulness of a witness are still too much in the experimental field for the courts to approve of their general use. The deception tests devised by scientists are of the following three broad types. The association reaction tests in which the time the subject takes to think of words associated with those in a list given him, some of which are neutral and some of which may evoke a guilty association, is carefully measured, the respiratory test, which is based upon the hypothesis that the breathing of the subject varies according to whether he is telling the truth, and the systolic blood pressure test. The instances in which such criteria have been subjected to judicial scrutiny are relatively infrequent. Those which have passed upon the question have held that the systolic blood pressure deception test for determining the truthfulness of testimony has not yet gained such standing and scientific recognition as to justify the admission of expert testimony deduced from tests made under such theory." The court could see no reason why, under the circumstances of this case, the results should have been admitted. There was no testimony offered indicating that there is at this time a general scientific recognition of such tests. Until it is established that reasonable certainty follows from such tests, it would be error to admit in evidence the result thereof. The judgment of conviction was affirmed—*People v. Brecler*, 2 V. IV (2d) 503 (Mich., 1942).

Medical Practice Acts Graduate of Foreign Medical School Denied Licensure—The Ohio medical practice act provides that an applicant, among other things must present a diploma from a medical institution in the United States in good standing, as defined by the board, at the time the diploma was issued, or a diploma or license approved by the board which conferred the full right to practice all branches of medicine or surgery in a foreign country. The petitioner in this case obtained his premedical education in the United States and thereafter received a diploma from the University of Lausanne, in Switzerland, which conferred on him the degree of Doctor of Medicine. Under the laws of that country no person other

than a Swiss citizen may be licensed to practice medicine. The petitioner returned to the United States and applied to the Ohio state medical board for permission to take the regular examination for a license to practice medicine. Permission to take the examination was denied and the petitioner commenced a mandamus action in the Supreme Court of Ohio to require the defendants, members of the medical board, to admit him to such examination.

The defendants demurred to the petition and the question presented for determination by the court was whether or not the petitioner's presentation of a diploma from the University of Lausanne in Switzerland required the defendants to permit him to take the examination. The petitioner contended that a citizen of Switzerland who came to this country and sought to take the medical examination would be permitted to do so under proper construction of our statutes, whereas a citizen of the United States who graduated from an accredited medical school in Switzerland but who could not be licensed to practice in that country would not be permitted to take the examination. Under the Ohio act, said the court, two things are necessary, (a) the diploma or license, as the case may be, must be approved by the board, and (b) such diploma or license must confer the full right to practice all branches of medicine and surgery in a foreign country. The act makes no distinction between an alien and a citizen and is a valid and constitutional enactment. Either a diploma or a license may be presented, and whichever is presented must be approved by the board. The right to approve exists at the time the diploma is presented, notwithstanding previous action as to the good standing of the institution which issued the diploma. The board had a right in the exercise of its discretion to withhold approval of the diploma. If, said the court, the act does an injustice, the appeal for relief must be made to the legislature. The defendants' demurrer to the plaintiff's mandamus petition was accordingly sustained, in effect upholding the action of the board in refusing to the petitioner the right to take the examination—*State ex rel. Anahs v. Hunsler*, 39 N. E. (2d) 851 (Ohio, 1942).

Medical Societies Jurisdiction of Court to Reinstate Expelled Member—About April 1933 certain members of the Kern County Medical Society, as taxpayers, instituted an action to enjoin the county supervisors from accepting at the county hospital patients who could afford to pay in whole or in part for necessary care and medical service. Injunctive relief was granted. Commencing in the year 1931 and each year to and including 1938 the Kern County Medical Society adopted a resolution providing that failure on the part of any member to resign from the staff of the Kern General Hospital "within a reasonable time while present unsatisfactory conditions exist in said hospital shall be construed as violation of ethics, and shall make such member liable to disciplinary action in accordance with the constitution and by-laws. The petitioner a member of the medical society, was on the staff of the hospital. Both in 1932 and in 1933 charges were filed against him for his failure to resign from the staff, but no disciplinary action was taken at that time. In 1934 the society adopted a new constitution and by-laws. The petitioner signed them along with the other members. Among other things the by-laws provided that "It is unprofessional for a physician to dispose of his services under conditions that make it impossible to render adequate service to his patient or which interfere with reasonable competition among the physicians of the community. To do this is detrimental to the public and to the individual physician, and lowers the dignity of the profession."

In September 1935 disciplinary proceedings were instituted by the society against the petitioner in which a violation of the quoted provision of the by-laws was alleged. It was charged that he had for several years participated in a political policy to monopolize the care treatment and hospitalization of the sick by the county of Kern at public expense by the unlawful use of the county hospital irrespective of the lawful right of patients to be treated at public expense, with the object and purpose of interfering with the reasonable competition among physicians in the community, that as a result of such political policy and practice the county hospital became overcrowded and understaffed so that it became impossible to render adequate service. It was also charged that the petitioner lent his coopera-
